In conclusion, satellite DNAs, which are both heavier and lighter than main band DNA, have been found in five crustacean species. A light satellite resembling "crab poly d(A–T)" in CsCl gradients has been found in the blue crab, *Callinectes*, but by various criteria this satellite has been shown in fact to be different from "crab poly d(A–T)". The measured T_m (Fig. 2*a*) of the (A+T)-rich satellite from *Callinectes* is that expected for a DNA with a G+C content of 27 per cent, and such a DNA would also have a density in neutral CsCl of 1.677 g/cm³ (ref. 18). Clearly, satellite DNAs of $\rho = 1.677$ g/cm³ (ref. 10) require additional analyses to determine their base compositions.

This investigation was jointly sponsored by the US National Institute of Child Health and Human Development (partly by a grant to M. S. K. as a University of

Fig. 2. Thermal dissociation of DNA of *Gecarcinus* and *Callinectes*. a, 40 μ g DNA isolated from the haemocytes of *Callinectes* (Δ — Δ); 20 μ g of DNA isolated from the testes of *Gecarcinus* (\bullet — \bullet); and a mixture of the two DNAs, 20 μ g *Callinectes* and 10 μ g *Gecarcinus* (\circ — \circ), were heated in SSC/10 in stoppered 1 ml. cuvettes in a Gilford spectrophotometer programmed for a 2° C temperature increase per min. The inset in a is an enlargement of the temperature range from 60–70° C. b, *Callinectes* (A+T)-rich satellite DNA was greatly enriched by centrifugation of total DNA in a preparative gradient of 7.7 M CsCl (refs. 4 and 6). 49 μ g of the material in the light band was concentrated to a volume of 1 μ l, dialysed against SSC/10, and its thermal dissociation was monitored (Δ — Δ). The hyperchromicity at 71° C arises from the main band DNA contaminating the preparation. Total DNA of *Gecarcinus* was melted as a control (\bullet — \bullet).

Dissociation of Haemoglobin Chesapeake into Subunits

AMONG the large number of human haemoglobin variants of known structure, most are functionally normal. Haemoglobin Chesapeake (α_2 92 Arg→Leu β_2) is the first one found in association with elevated whole blood oxygen affinity and familial erythrocytosis. By contrast with haemoglobin A, isolated haemoglobin Chesapeake displays a six-fold increase in oxygen affinity and a marked reduction in haem-haem interaction (Hill's coefficient $n = 1.3$), but a normal Bohr effect². In the past two years, other variants with similar properties have been reported, but none has been studied as extensively as haemoglobin Chesapeake. These mutants provide considerable information relating the structure and function of haemoglobin, for their amino-acid substitutions are likely to be at sites crucial to the normal function of the molecule. It is of considerable interest that in four of these haemoglobins (Chesapeake, J-Capetown, Yakima and Kempsey), the substitutions are located in the area of contact between the α_1 and β_2 chains³. Three-dimensional models constructed from the X-ray crystallographic data of Perutz and associates indicate that, during oxygenation, there is considerable movement of the β chains relative to the α chains at this interface⁴. It is likely that the symmetrical dissociation of oxyhaemoglobin into $\alpha\beta$ dimers also occurs at the $\alpha_1\beta_2$ contact areas^{5,6}.

The extent of subunit dissociation of haemoglobin Chesapeake, compared with that of haemoglobin A, was studied by analytical ultracentrifugation. Previously, gel filtration data indicated that the dissociation of the liganded forms of haemoglobin Chesapeake into subunits was qualitatively less than haemoglobin A (ref. 7). Haemoglobins Chesapeake and A were prepared from a fresh haemolysate on carboxymethylcellulose as described by Charache *et al.*¹. Our results enable us to compare A and Chesapeake haemoglobins isolated on the same column. A Spinco model E analytical ultracentrifuge was

used, with a Corning 2-61 red filter and Kodak 1-D red-sensitive plates. Sedimentation velocity measurements were done at 50,740 r.p.m., 15° C, on 0.2 per cent phosphate-free haemoglobin solutions in 30 mm aluminium cells (Table 1). The use of a negative wedge window allowed specimens of haemoglobins A and Chesapeake to be run simultaneously. Subunit dissociation was enhanced in the presence of increasing concentrations of NaCl. Both the oxy and carboxy forms of haemoglobin Chesapeake had relatively higher $S_{20,w}$ values than haemoglobin A (Table 1), indicating that in high NaCl concentrations, the liganded forms of haemoglobin Chesapeake dissociated less readily into subunits. By contrast, the $s_{20,w}$ values of the deoxy form of the two haemoglobins were the same in 2.0 M NaCl, although higher than the carboxy values. Because of its high oxygen affinity, haemoglobin Chesapeake could not be maintained in the deoxygenated state during the centrifuge run unless 1.0 mM sodium dithionite was present. To minimize possible side reactions⁸, the addition of dithionite to deoxyhaemoglobin and the transfer to the cell were performed in strict anaerobic conditions. The $s_{20,w}$ values of deoxyhaemoglobin A in 2.0 M NaCl were the same whether or not dithionite was present. The data (Table 1) confirm earlier observations that deoxyhaemoglobin A dissociates less readily than the liganded haemoglobin^{9,10}.

Recently, Edelstein and Gibson have shown that because of incomplete permeation of salt inside the haemoglobin molecule, a flotation effect reduces sedimentation in high NaCl concentrations¹¹. Thus these $s_{20,w}$ values in 1.0 and 2.0 M NaCl overestimate the extent of subunit dissociation. Nevertheless they show qualitative differences between the liganded forms of haemoglobins A and Chesapeake.

To examine the subunit dissociation of these haemoglobins at a more physiological ionic strength (0.1 M NaCl), a much lower protein concentration was required. Use of interference optics allowed a haemoglobin concentration of 0.03 per cent. Weight average molecular weights were determined in triplicate by the method of Yphantis, using a 12 mm double sector aluminium epoxy cell¹². Runs were done at 25,980 r.p.m. for 16 h at 10° C. The spectra of carboxyhaemoglobin in the cell following centrifugation revealed no auto-oxidation. The mean molecular weight of haemoglobin Chesapeake was 64,900, significantly higher than the mean value of 60,800 obtained for carboxyhaemoglobin A ($0.01 < P < 0.05$).

Intact α chains of carboxyhaemoglobins A and Chesapeake were prepared by the method of Bucci and Fronticelli¹³. Mercury was removed from globin sulphhydryl groups by thioglycollate¹³. Spectrophotometric oxygen equilibria experiments were done on 0.4 per cent haemoglobin solutions in 0.1 M NaCl-0.05 M bis Tris buffer (pH 7.2) at 10° and 20° C. The mutant α chains of haemoglobin Chesapeake consistently showed a somewhat lower oxygen affinity than normal α chains from haemoglobin A. This difference was not related to any detectable aggregation of α chains as shown by the $s_{20,w}$ values in Table 1. Thus the high ligand affinity of the Chesapeake tetramer does not seem to be related to the immediate haem environment of the mutant α chain, but rather to interaction between the subunits.

These results indicate that liganded forms of haemoglobin Chesapeake dissociate into subunits less readily

than haemoglobin A. Because the amino-acid substitution in haemoglobin Chesapeake is at the $\alpha_1\beta_2$ contact area, these data strengthen the evidence that the symmetrical dissociation of the liganded tetramer into $\alpha\beta$ dimers is at this interface. It is likely that the increased energy of binding between subunits of the liganded form of haemoglobin Chesapeake favours this conformational isomer over the deoxy form and contributes to the high oxygen affinity of haemoglobin Chesapeake. The thermodynamic linkage between ligand affinity and subunit interaction has been stressed¹⁴⁻¹⁶.

According to recent data of J. Greer, difference Fourier of haemoglobins Chesapeake and A showed that the oxy forms differ extensively in conformation whereas the deoxy forms differ only in the known amino-acid substitution ($\alpha 92 \text{ Arg} \rightarrow \text{Leu}$)¹⁷. But the deoxy forms probably differ in conformation as well, as shown by sulphhydryl reactivity and ultraviolet difference spectra². Recent nuclear magnetic resonance data of Ho and associates indicate that both the oxy and deoxy forms of haemoglobin Chesapeake differ significantly from haemoglobin A (ref. 18).

I thank Dr Robin W. Briehl in whose laboratory this work was done, and Dr Samuel Charache who provided blood specimens. This work was supported in part by Dr Briehl's grant from the National Heart Institute.

¹³C Nuclear Magnetic Resonance Spectrum of Gramicidin S-A, a Decapeptide Antibiotic

ALTHOUGH proton magnetic resonance spectroscopy has improved our knowledge of the structure and function of biopolymers, especially complex peptides and proteins¹, it has not yet solved such problems as determining the conformation of a protein in solution. The nearest approach has been the analysis of the spectrum of gramicidin S-A², a peptide of molecular weight 1,120 (Fig. 1). The technique used there is theoretically applicable to biopolymers of higher molecular weight, but the experimental difficulties are almost insurmountable.

We report here the ¹³C nuclear magnetic resonance (NMR) spectrum of gramicidin S-A and our assignment of the various ¹³C chemical shifts. Our data suggest that the study of ¹³C spectra is entirely feasible and, moreover,

that ^{13}C spectra are more easily interpretable than proton spectra.

In naturally occurring molecules the predominant carbon isotope is ^{12}C which has no spin and does not exhibit magnetic resonance. Although the ^{13}C isotope has a natural abundance of only 1.1 per cent, it has a spin of $1/2$, and ^{13}C spectra of simple molecules³, steroids⁴ and some amino-acids^{5,6} have been recorded in enriched samples and at natural abundance. Nobody has yet reported the ^{13}C spectrum of a protein or any molecule comparable in size to gramicidin S-A, in natural abundance or otherwise.

We recorded the ^{13}C NMR spectrum of gramicidin S-A at 25.15 MHz with time averaging to enhance the signal to noise ratio. The spectrum extends over 160 p.p.m. of the applied field relative to ^{13}C S_2 as external standard. The complicating feature of ^{13}C -proton coupling was eliminated by noise decoupling and ^{13}C - ^{13}C interactions are not seen, for the chance that an individual ^{13}C atom will have another ^{13}C atom adjacent to it is approximately 1 in 10^4 . Each carbon thus appears as a singlet. There seems to be no evidence of ^{14}N - ^{13}C coupling, but this feature requires more study. Samples were run in 12 mm tubes with no spinning. Concentrations varied from 300–500 mg/2 ml.

The spectra are readily divided into well-separated regions: (a) carbonyl carbons (19–24 p.p.m.), (b) aromatic heteroaromatic carbons (50–70 p.p.m.), (c) C_α carbons (130–140 p.p.m.), (d) C_β carbons (150–165 p.p.m.), and (e) C_γ and methyl carbons (165–180 p.p.m.).

Fig. 2 shows the ^{13}C spectrum of gramicidin S-A in two solvents. Rigorous assignments of individual carbon atom resonances will require more exacting experiments, but all of the general features can be discerned. The ^{13}C spectrum of gramicidin S-A in either methanol or DMSO should have a total of twenty-eight lines, including nineteen from the side chain and C_α carbon atoms. In addition there should be four aromatic lines (ortho, meta, para and bridge phenylalanine atoms) and five carbonyl (C_0) lines. This can be regarded as agreeing with the results found if one accepts that (a) the ^{13}C DMSO peak obscures one line, (b) there are four lines in the 166–170 p.p.m. region in DMSO, (c) the four single lines at 170.0 p.p.m. (Fig. 2A), 167.5, 168.9 and 172.5 p.p.m. (Fig. 2C) are each caused by two carbon atoms whose lines are superimposed, and (d) one line in the C_0 region is doubled because of superimposition of two resonances. We thus obtain a complete carbon atom count for the whole molecule, assuming C_2 symmetry.

Our assignment of peaks in the spectrum to individual carbon atoms is based on a comparison of peak positions with the ^{13}C chemical shifts found for the N-acetyl amino-acid methyl esters. Individual peaks in the monomer spectra were assigned by comparison with the spectra of the amino-acids, both as observed^{5,6} and as calculated from Grant's rules^{7,8}. Agreement between observed and predicted chemical shifts for amino-acids is excellent, as shown in Table 1.

The ^{13}C spectra of the five amino-acids comprising gramicidin S-A (in H_2O) and their N-acetyl methyl ester derivatives are shown in Table 1. Although the peaks of the amino-acid and the ester do not superimpose, the differences observed are remarkably constant from amino-acid to amino-acid. All of the side chain resonances of the derivatives are found 1.5 ± 0.9 p.p.m. downfield from the corresponding resonances in the free amino-acids, presumably because of the difference in solvent bulk magnetic susceptibilities. The C_α carbon resonances, however, shift upfield 2.0 ± 0.5 p.p.m. because of charge redistribution in the derivatives.

Individual carbon assignments for the side chain and C_α carbon region are shown in Table 1. There was no difficulty in making general assignments, although in several cases minor ambiguities were apparent. None of these caused confusion. The lowest-field pair of lines

Fig. 1. Schematic drawing of the three-dimensional structure of gramicidin S-A, cyclo (-Phe-Pro-Val-Orn-Leu-), proposed from proton NMR studies². All ω angles are 0° except for Leu = 10° . The ϕ angles of Val, Orn, Leu = 30° , Phe = 150° . The ψ angles of Val, Orn, Leu = 0° , Phe and Pro = 130° .

clearly belongs to the proline and valine C_α carbon atoms but, because the monomer chemical shifts in this case are so close, it is not possible to decide with certainty which belongs to valine and which belongs to proline. Similar problems were encountered with the next pair of lines to higher field, and with the higher-field C_β and

‡ All positions are chemical shifts in p.p.m. upfield from $^{13}\text{CS}_2$.

§ N-acetyl amino-acid methyl esters in DMSO.

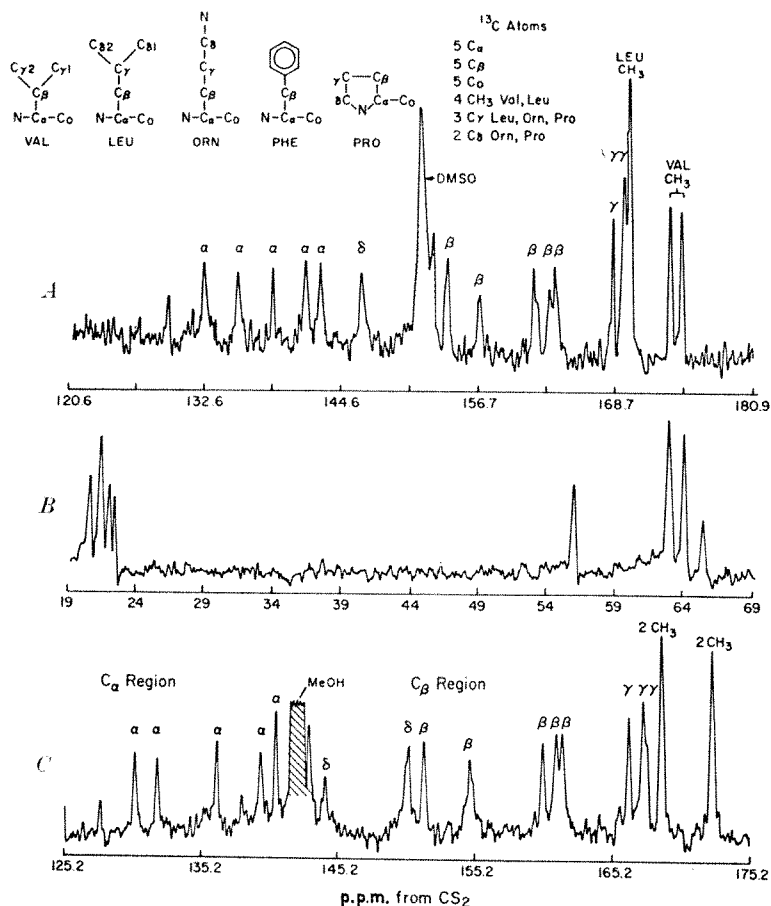

Fig. 2. The natural abundance ^{13}C NMR spectrum of gramicidin S-A. A, The high-field part of the spectrum in DMSO; B, the low-field part in DMSO; C, the high-field part in methanol. All chemical shifts are in p.p.m. upfield from $^{13}\text{CS}_2$ as external standard.

lowest-field C_β . Further, the three high-field C_β carbons are too close to one another to permit unambiguous assignments, and so are the three C_γ carbons. None of the chemical shifts is displaced significantly from the value found for the corresponding N-acetyl amino-acid methyl ester carbon. We now have enriched ^{13}C amino-acids available for selective incorporation studies to remove these difficulties.

Unfortunately, the carbonyl resonances fall within too narrow a range to be assigned at present. While carbonyl carbon resonances have been studied^{3,10,11}, insufficient is known for accurate predictions in this region. The phenyl-alanine lines may be assigned empirically as (low-field to high-field): bridge, ortho, meta, para.

The symmetry of gramicidin S-A is unequivocally C_2 from this spectrum, in agreement with the deduction from the proton spectrum². The five pairs of residues yield only five carbonyl, five C_α and five C_β chemical shifts. There is some interest in the two methyl group ^{13}C lines of valine. These groups are not magnetically equivalent, so two lines are to be expected, but the chemical shift difference between them is observed to vary from amino-acid to derivative to gramicidin. This can imply that the valine side chain has different average rotational conformations in the three cases. Proton spectra also revealed this difference². The $J_{\alpha\beta}$ proton coupling constant in valine alone is 6.5 Hz, but it is 9.0 Hz in gramicidin S-A, showing that in the latter the *trans* isomer predominates, that is, the isomer with the α and β protons *trans* to one another.

We now consider the relative heights and intensities of the various ^{13}C lines in the NMR spectra. There should be a general enhancement of all ^{13}C resonances on noise decoupling of protons because of the Nuclear Overhauser

Effect⁶; and the enhancement factor of 2.988 is theoretically possible wherever the ^{13}C relaxation mechanism is dominated by proton- ^{13}C dipole-dipole coupling⁹. Large deviations from this figure will be found only where the ^{13}C nucleus is not directly bonded to a proton or where the ^{13}C -H separation greatly exceeds that of a normal carbon-hydrogen bond. In our spectra of the N-acetylamino-acid methyl esters, the intensities of the ^{13}C lines are equal. This is not the case with gramicidin S-A. Because time averaging was necessary and variable RF power spectra were not taken, we are unable to explain these findings. We hope that the intensity relationships will help to identify chemical shifts⁹ and, when properly identified, yield information on relaxation times, transition probabilities and the molecular environment of the various carbon atoms in the molecule.

^{13}C NMR spectroscopy thus has strong advantages over proton spectroscopy in the study of complex peptides and, hopefully, proteins. In natural abundance, with noise decoupling of protons, the spectra obtained are much simpler than those for proton NMR. The simplicity of the spectrum and the near predictability of chemical shifts make assignments somewhat easier. The spectra are readily divided into well-separated regions: (a) carbonyl carbons, (b) aromatic-heteroaromatic carbons, (c) C_α carbons, (d) C_β carbons, and (e) C_γ and methyl carbons. Any slight overlap between these regions is not enough to interfere seriously with assignments. Specifically enriched ^{13}C spectra and spin-coupled and coherently decoupled spectra will confirm and complete the assignments.

^{13}C NMR also promises to lessen the problem of dipole-dipole line broadening of high molecular weight species such as proteins. Because of the smaller magnetic moment of the ^{13}C nucleus, ^{13}C line widths are theoretically only about one-sixteenth as susceptible to this form of line broadening as proton line widths.

Release from Density Dependent Growth Inhibition by Proteolytic Enzymes

CONFLUENT chick embryo cells in culture grow much more slowly than do sparse cells in conditions where significant depletion of the medium is avoided¹⁻³. Because an important factor regulating growth seems to be the population density, this phenomenon is called density dependent inhibition of growth⁴. When a thin scratch is made in a slowly growing confluent culture of chick embryo cells, the cells adjoining the scratch begin to grow rapidly and

Fig. 1. Rate of incorporation of ³H-thymidine (A) and mitosis (B) and increase in cell number (C) in the first 24 h following the addition of trypsin. 1×10^6 chick embryo cells from trypsinized primary cultures were added to 60 mm plastic Petri dishes in medium 199 plus 2 per cent tryptose phosphate broth and 2 per cent chicken serum. After 40 h of incubation at 38° C the cultures were fully confluent and 3 μ g/ml. of crystalline trypsin (Sigma) was added to the medium. At intervals the cultures were labelled with 0.25 μ Ci/ml. of ³H-thymidine for 1 h and the radioactivity insoluble in 5 per cent trichloroacetic acid was counted. The fraction of cells in mitosis was determined by microscopic count after fixation with Bouin's solution and staining with Harris's haematoxylin stain. The number of cells per dish was determined after trypsinization by counting in a Coulter electronic counter.

Fig. 2. Rate of incorporation of ³H-thymidine for a 4 day period after trypsin was added to the medium. The procedures were the same as in Fig. 1 except that 5×10^5 cells were plated in Scherer's medium, the cells were incubated for 72 h before treatment, and labelling was done at 24 h intervals.

continue to do so until confluence is restored³. Growth of confluent cells can also be stimulated by the addition of a macromolecular component of serum⁵. We now report that the addition of proteolytic enzymes to the medium of inhibited cells in concentrations too low to cause cell detachment stimulates rapid growth among the cells.

A concentration of 3 μ g/ml. of crystalline trypsin (Sigma) was sufficient to release cells from growth inhibition when added to the medium of confluent, growth inhibited cultures (Fig. 1). The only visible effect of this concentration of trypsin was to increase slightly the refractility of the cells. Three hours after the addition of trypsin an increase in the rate of incorporation of ³H-thymidine per cell into acid insoluble material was observed. The rise in the rate of incorporation of ³H-thymidine in the treated cultures correlated with later increases in mitotic rate and total cell number. This correlation justified the use of ³H-thymidine incorporation as an index of the rate of cell multiplication. The maximal rate of incorporation of ³H-thymidine per cell, twenty-one-fold higher than the untreated control, occurred 6-7 h after the addition of trypsin. It then decreased somewhat to a rate roughly ten-fold higher than that of the untreated cultures and this difference in rate continued until the termination of the experiment at 21 h. Autoradiographic studies show that this increased rate of incorporation in the treated cultures was the result of an increased fraction of the population incorporating ³H-thymidine rather than of an increased rate of incorporation in a constant fraction of the population (Table 1). At the time of maximal response 53 per cent of the treated cell population and only 2.9 per cent of the untreated population incorporated ³H-thymidine during the 1 h labelling period. This peak probably resulted from a partially synchronous release from inhibition. Mitosis reached a maximum in the treated cultures at 11 h. Between 8 and 20 h after the addition of trypsin, the number of cells in the treated population doubled. During the 21 h time-span of this experiment, the rate of incorporation of ³H-thymidine and mitosis in the untreated cultures remained essentially constant and only a 15 per cent increase in total cell number occurred. The presence in the medium of 3 μ g/ml. of trypsin can maintain, in some

experiments, an increased rate of ^3H -thymidine incorporation relative to untreated controls for up to 96 h (Fig. 2).

The stimulation was proportional to the concentration of trypsin up to 2 $\mu\text{g}/\text{ml}$. and was then independent of further increases in concentration up to 15 $\mu\text{g}/\text{ml}$. (Fig. 3). At higher concentrations the cells were removed from the dish. At least two other proteases, pronase and ficin, which are less specific in their activities than trypsin also release cells from growth inhibition (Table 2).

Table 1. FRACTION OF CELLS INCORPORATING ^3H -THYMIDINE AS DETERMINED BY AUTORADIOGRAPHY

Hours after addition of trypsin	0	2.5	4.5	6.5	8.5	10.5	12.5	14.5	16.5	20.5
Per cent cells labelled	2.9	10.6	23.7	32.7	53.0	30.8	23.1	20.1	23.5	16.6

Same experiment as Fig. 1. The cells were labelled for 1 h with 1 $\mu\text{Ci}/\text{ml}$. of ^3H -thymidine, fixed with Bouin's solution and covered with emulsion. Before radioactivity was counted they were stained with Harris's haematoxylin stain.

Table 2. RATE OF INCORPORATION OF ^3H -THYMIDINE INTO FICIN AND PRONASE TREATED CULTURES

Treatment	c.p.m./ 10^4 cells
Control	600
1 $\mu\text{g}/\text{ml}$. pronase	3,040
3 $\mu\text{g}/\text{ml}$. trypsin	4,180
Control	1,070
5 $\mu\text{g}/\text{ml}$. ficin	3,000
1.25 $\mu\text{g}/\text{ml}$. ficin	1,570
1.25 $\mu\text{g}/\text{ml}$. ficin	1,320
3 $\mu\text{g}/\text{ml}$. trypsin	11,400

Cultures containing 1.6×10^6 cells were prepared as in Fig. 1. After incubation for 36 h the indicated amounts of enzymes were added and ^3H -thymidine incorporation was measured 20 h later.

The rate of incorporation of ^3H -thymidine per cell was inversely proportional to the population density of cells in a culture (Fig. 4). When trypsin was present in the medium, however, the rate of incorporation was much less dependent on population density. Trypsin reduced the rate of incorporation per cell of sparse cultures (fewer than $4 \times 10^5/60$ mm dish) and increased it in dense cultures (more than $4 \times 10^5/60$ mm dish) to a rate almost independent of density.

An experiment was done to determine whether trypsin stimulates growth by acting directly on the cells or by producing a stimulatory product in the medium. Medium was first incubated with trypsin and then an excess of soybean trypsin inhibitor was added before placing the mixture on inhibited cultures. Trypsin treated medium failed to stimulate ^3H -thymidine incorporation if soybean

Fig. 3. Incorporation of ^3H -thymidine as a function of the concentration of trypsin in the growth medium. The procedures were the same as in Fig. 2, the trypsin was added at the indicated concentrations, and ^3H -thymidine incorporation was measured 18 h later.

Fig. 4. Incorporation of ^3H -thymidine as a function of cell density. Cultures were prepared at six densities according to the procedures of Fig. 1. Trypsin (3 $\mu\text{g}/\text{ml}$.) was added 4 h after seeding. At 24 h after seeding, cell number was determined by trypsinization and Coulter counting and ^3H -thymidine incorporation was measured.

trypsin inhibitor was added but did so if the inhibitor was omitted (Table 3). Significantly, the inhibitor did not prevent the stimulation of cells by pronase. These results show that trypsin acts directly on the cells to stimulate their growth and that it does so through its specific proteolytic activity.

Table 3. EFFECT OF SOYBEAN TRYPSIN INHIBITOR ON GROWTH STIMULATION PRODUCED BY TRYPSIN AND PRONASE

Medium included in agar overlay	c.p.m./ 10^4 cell
Control	2,394
Pretreated with trypsin	11,029
Pretreated with pronase	4,625
Control plus inhibitor	2,290
Pretreated with trypsin plus inhibitor	2,956
Pretreated with pronase plus inhibitor	4,062

A previously described⁴ agar overlay assay was used. Medium was incubated for 30 min at 38°C at pH 7.2 with either 3 $\mu\text{g}/\text{ml}$. trypsin or 1 $\mu\text{g}/\text{ml}$. pronase and then mixed with 20 $\mu\text{g}/\text{ml}$. soybean trypsin inhibitor (Worthington) and added to the cells. 24 h later ^3H -thymidine incorporation was measured.

Because trypsin is not taken up into living cells⁷, disrupts monolayers without killing cells, and is known to alter various components of the plasma membrane⁸⁻¹⁰, its growth stimulating effect probably stems from limited proteolysis of the cell surface. The possibility that the growth stimulation results from the removal of cells from the surface of the dish was excluded by microscopic examination which showed that the number of nuclei per microscopic field did not decrease at any time after the trypsin was added.

There are two plausible but not mutually exclusive explanations for the effect of trypsin. One is that the permeability of the cells to certain growth regulating elements such as ions¹¹ or nutrients¹² is altered by the action of trypsin. The other is that trypsin inactivates surface recognition sites involved in sensing the proximity of other cells. There is no basis at present to choose between the two possibilities.

The stimulation of growth produced by proteases in culture raises the question whether these or related enzymes play a part in growth regulation in the natural state. Some findings which support this notion are the stimulation of salivary gland growth by proteases¹³ and the existence of peptidase and esterase activities in preparations of the skin, epithelial, mesenchymal and nerve growth factors¹⁴⁻¹⁶. Peptidases are particularly abundant in the periphery of many tumours where stromal and vascular stimulation occurs¹⁷, and Rous sarcoma virus transformed cells release a growth stimulating factor which has some properties suggestive of proteases⁶. A further analysis of the biological significance of proteases in growth regulation should therefore be studied further.

This investigation was supported by a US Public Health Service research grant from the National Cancer Institute

and a training grant from the Institute of General Medical Sciences.

Inhibition of Bone Marrow Colony Formation by Normal and Leukaemic Human Serum

A FACTOR is present in the serum and urine of mice and humans which can stimulate the formation of granulocytic and macrophage colonies by mouse bone marrow cells in agar culture¹⁻³. Levels of this colony stimulating factor (CSF) can be assayed in bone marrow cultures because of the sigmoid relationship between CSF concentration and colony numbers³. Previous studies showed that serum CSF levels were elevated in mice with various types of leukaemia^{1,4}. Although serum colony stimulating activity seemed to be high in some patients with leukaemia⁵, a direct comparison of CSF levels in normal and leukaemic human sera was prevented by an inability to detect CSF in normal human serum.

During studies on the fraction of CSF from mouse serum, it was found that a lipoprotein fraction was present in serum which could inhibit colony stimulation by CSF and thus mask the detection of CSF. Although this inhibitory material was non-dialysable, it precipitated from the serum during dialysis of the serum for 3 days against water and could subsequently be removed by centrifugation⁶. Application of this dialysis procedure to normal human sera has allowed low levels of CSF to be detected in all of 50 sera assayed, mean colony counts of ten (range 3-25) being obtained using 0.1 ml. of serum with 75,000 C57Bl bone marrow cells.

An assay system has now been developed for inhibitor levels in human sera based on the capacity of the test serum to inhibit colony formation stimulated by standard pools of highly active (dialysed) human sera from patients with renal disease. Assays were performed in 35 mm Petri dishes using 1 ml. cultures of 0.3 per cent agar in Eagle's medium containing 75,000 C57Bl bone marrow cells. The culture technique has been described in full elsewhere⁴. In the assay, 0.05 ml. of the active serum pool and 0.1 ml. of the test serum were mixed in the Petri dish before the addition of the agar-medium containing bone marrow cells. Colony counts were performed on replicate culture after incubation for 7 days at 37°C in 10 per cent CO₂ in

Fig. 1. Distribution of inhibitor levels in normal sera and sera from patients with acute granulocytic leukaemia, before and after dialysis. Number of sera assayed indicated in parentheses.

air, and inhibitor levels were expressed as the mean percentage reduction in colony counts compared with counts in control cultures containing the active serum alone. Control colony counts ranged from 40-75 per culture according to the active pool used.

A survey of 187 sera from healthy blood donors aged 20-65 yr revealed that 98 per cent of the sera had inhibitor levels ranging from 50-100 per cent (Fig. 1) and this was accepted as the normal range. Tests on forty-two of these sera after dialysis against water for 3 days showed that inhibitor levels had been reduced to levels ranging from 0-60 per cent and 85 per cent of the dialysed sera showed inhibitor levels below 50 per cent. Parallel assays were made on 120 sera from 38 adult patients with acute granulocytic leukaemia. Inhibitor levels in these leukaemic sera had a bimodal distribution, 46 per cent of the sera having inhibitor levels within the normal range whereas the remainder had subnormal levels and 36 per cent of the sera exhibited no detectable inhibitory activity. Dialysis of leukaemic sera reduced inhibitor levels in most, but occasional sera persisted in exhibiting 100 per cent inhibition of colony formation, a phenomenon not evident with dialysed normal serum.

Direct and indirect evidence suggests that CSF operates in the body as a regulator of granulopoiesis and macrophage formation⁷, but the biological significance of the present inhibitors is quite unknown. It is possible that the inhibitory activity observed is an *in vitro* artefact, but the inhibitors in human sera were not toxic for colony cells and did not inhibit colony formation stimulated by mouse CSF. Further work is required to determine the incidence of low inhibitor levels in various disease states and the clinical significance of fluctuations in serum inhibitor levels is being investigated in a sequential study on leukaemic patients. One possibility is that these inhibitors may operate *in vivo* to modulate, or balance, the stimulating effects of CSF on granulocyte and macrophage formation. If so, then the low inhibitor levels in acute

granulocytic leukaemia may be of significance in contributing to the abnormal granulopoiesis in these patients.

We thank Dr F. W. Gunz, of the Kanematsu Institute, Sydney, for supplying some of the leukaemic sera used in these studies and Misses S. Stevens and V. Scarfe for technical assistance.

Importance of Immunologically Competent Cells in Contact-induced Cytotoxicity

It is not yet clear whether the cytotoxicity observed when target cells and allogeneic lymphoid cells are cultured together *in vitro*^{1,2} is mediated by an immunological mechanism. Cell death has been attributed to contact with the antigenically or structurally incompatible lymphocyte cell surface rather than by any conventional immunological reaction^{2,3}. Thus any cell type carrying foreign histocompatibility antigens would be able to cause target cell death. The following experiments were carried out to test this hypothesis.

Mouse ascites tumours (BP8 of C3H origin, or Sarcoma 1 of A strain origin) were used as the source of target cells. 10^6 tumour cells were incubated for 24 h at 27°C in Hanks balanced salt solution with 10 per cent calf serum, and the medium was then changed to medium 199 with 10 per cent calf serum, and phytohaemagglutinin when BP8 target cells were used. 10×10^6 effector cells were added to the tumour cell cultures, and incubation was continued for a further 48 h. The supernatant was removed, replaced with 0.1 per cent eosin, and living (unstained) and dead (stained) cells were counted. Each combination of cells was set up in triplicate and most readings were done "blind".

80 to 85 per cent target cells were viable after incubation alone or with syngeneic lymph node cells. 50 to 55 per cent BP8 cells (Table 1) and 60 to 65 per cent Sarcoma 1 cells (Table 2) survived incubation with allogeneic or semi-

Table 2. EFFECTIVENESS OF LYMPHOID CELLS (10×10^6) FROM IMMUNOLOGICALLY INCOMPETENT MICE IN PRODUCING DEATH OF SARCOMA 1 (A STRAIN) TARGET CELLS (10^6)

Effector cell donor	Treatment of donor	Time after treatment	Per cent living cells after 48 h
—	—	—	83
Syngeneic	—	—	85
Allogeneic	—	—	62
Allogeneic	Tolerance induced with A cells	20 weeks	84
Allogeneic	Tolerance induced with A \times C3H cells	20 weeks	83

Allogeneic	ALS treated	3 weeks	64

syngeneic lymph node cells. Using Snedecor's variance ratio test these results were found to be highly significant.

Experiments with non-lymphoid effector cells yielded negative results (Table 1). Allogeneic red blood cells had no effect on the target cells, and epidermal cells (prepared by tryptic digestion of mouse tail skin) were also non-cytotoxic. Although sarcoma cells were slightly cytotoxic, this effect was also observed with syngeneic sarcoma cells and probably resulted from the development of generally toxic culture conditions, such as exhaustion of the medium by the large number of rapidly metabolizing cells. Table 1 also shows the cytotoxic ability of lymphoid effector cells. Spleen cells were competent to cause significant cytotoxicity, but to a lesser degree than lymph node cells. Thymus and bone marrow cells were both inactive. Cells from newborn mice and one week old mice did not kill target cells, but by the second week they had evidently become competent to do so.

The cytotoxic capacity of effector cells from tolerant mice is shown in Table 2. Lymphocytes from C3H mice made tolerant to the target genotype (A strain) did not kill target cells, but lymphocytes from mice made tolerant to another genotype (CBA) remained cytotoxic. Because the tolerant mice were cellular chimaeras and might have many lymphocytes of donor origin (in the former case syngeneic with target cells), chimaera tests were carried out to determine the number of donor cells. One was an *in vitro* cytotoxicity test using an anti-C3H antiserum raised in A strain mice, and the other was an *in vivo* method designed by Mitchison⁴ and modified by Brent and Gowland⁵, who used the test quantitatively. Both tests confirmed the results of Brent and Gowland⁵, only about 5 per cent of the cells being of donor origin. Later, tolerance to the target cell genotype was induced with semi-syngeneic (A \times C3H) cells, and in sufficient numbers these would be cytotoxic (Table 1); however, cells from these animals had no cytotoxic effect. It is clear therefore that the number of donor cells present cannot account for the observations, and that the host cells must have become non-reactive as a result of neonatal exposure to target cell antigens.

To avoid the complication of cellular chimaerism neonatally thymectomized mice were used as effector cell donors (Table 2). Cells from these animals did not have any cytotoxic effect, but cells from sham-thymectomized animals reacted normally.

The effects of lymph node cells from mice treated with antilymphocytic serum (ALS) are shown in Table 2, the effector cells being taken at weekly intervals after treatment. The results show that their cytotoxic capacity was at first suppressed, but that it returned within 3 weeks. In parallel *in vivo* experiments, lymph nodes were taken from mice at weekly intervals after treatment and injected into hybrid recipients which were examined for splenomegaly ten days later. It was found that cells taken 1 and 2 weeks after ALS treatment did not cause splenomegaly, whereas cells taken at week 3 were as effective as cells from untreated mice in producing splenomegaly. This indicates that the return of competence detected in the *in vivo* system corresponds to the return of the cytotoxic capacity of the cells *in vitro*.

These studies suggest that only cells capable of mounting an immunological response can cause contact-induced

Table 1. EFFECTIVENESS OF VARIOUS TYPES OF EFFECTOR CELLS (10×10^6) IN PRODUCING DEATH OF BP8 TARGET CELLS (10^6)

cytotoxicity. Immunologically incompetent cells, both lymphoid and non-lymphoid, were not cytotoxic. The finding that lymphoid cells became reactive after the first week of life agrees with work by Brent and Gowland⁶, which indicated that at least some mice do not have their full complement of competent cells until after this time. The fact that lymphoid cells from mice tolerant to the target cell genotype were not cytotoxic, unlike cells from mice tolerant to another genotype, strongly suggests a specific immunological reaction occurring *in vitro*. Möller and Lapp have found⁷ that lymphoid cells from tolerant mice can destroy a monolayer of the strain to which tolerance has been induced. Maculla^{8,9} found that, in the case of some tissues, the embryonic organs possess antigens absent from adult tissue; because Möller and Lapp used embryonic tissue as a source of target cells, and induced tolerance with adult spleen cells⁷, this might explain their observations of a cytotoxic effect with lymphoid cells from the tolerant animals.

The only result indicative of a non-immunological mechanism is the cytotoxicity obtained with hybrid lymphoid cells which should be unable to react against parental strain target cells. This "hybrid effect" could be caused by mechanisms other than that proposed by Möller and Möller²; the tumours may possess "specific" or viral-induced transplantation antigens, or minor alloantigens caused by genetic divergence in the strain of origin, and F₁ hybrids may react more strongly than the parental strain because of hybrid vigour. Cudkowiec has proposed¹⁰ that all antigens present in the two parental strains may not necessarily be expressed fully in the F₁ hybrid. These possibilities would explain hybrid cytotoxicity on an immunological basis, and the effect is therefore being investigated further.

I thank the Medical Research Council for supporting this research, and Professor L. Brent for his generous advice.

Single Hit Aetiology of Human Minor Congenital Malformations unassociated with Major Congenital Malformations

MINOR birth defects can be defined as anatomical variants which occur at low frequency in the normal population and, as distinguished from major malformations, have no clinical or cosmetic effects *per se*. Many syndromes associated with major defects such as the trisomies and rubella embryopathy also have a high incidence of minor malformations. Conversely, almost all minor defects which have been studied clinically are known to be more frequent in individuals with major malformations. The latter types of malformations have been shown to cluster in the sense that an individual with a major defect in one

organ or system is more likely than an individual chosen at random to have a significant defect elsewhere¹. But we have found that minor malformations in individuals without major malformations do not show such a tendency to cluster but rather are independent. Furthermore, our subsequent analysis of published data of other workers which bear on this problem supports this conclusion.

Between July 7 and September 5, 1969, 202 white newborn infants in a local hospital were examined by one of us (J. J. P.) using the methods of an earlier study¹. Babies were selected only by their presence in the hospital on a weekday during that time and the availability of maternal age and birth weight from their records at the time of examination. We specifically looked for anomalies which had been classified as minor malformations by Marden *et al.* (Tables 3 and 4 in ref. 1), at Madison, Wisconsin. Sydney lines, flat nasal bridges and hyperextensible thumbs were also scored as minor defects. The decision to include these additional defects was made before the Poisson distribution was calculated. The analysis here is limited to those 200 babies in whom no major malformations were detected.

In Table 1 the distribution of minor malformations and the comparison with the expected findings on the assumption of a Poisson distribution are given. Table 2 provides a brief summary of the observations of the Albany and Madison studies.

Table 1. OBSERVED AND EXPECTED DISTRIBUTION OF MINOR ANOMALIES IN MADISON AND ALBANY STUDIES

No. of anomalies per baby	Madison†		Albany§	
	Observed*	Expected†	Observed	Expected†
0	3,713	3,723.4	121	118.9
1	574	554.8	58	61.8
2	33	41.3	17	16.1
3	2	2.1	4	2.8

* Calculated from Table 2 of the Madison study assuming three anomalies in each of the two babies listed as having three or more anomalies.

† Calculated from Poisson distribution².

‡ Goodness of fit $\chi^2 = 2.363$, $0.50 > P > 0.25$ (2 d.f.).

§ Goodness of fit $\chi^2 = 0.827$, $0.75 > P > 0.50$ (2 d.f.).

Table 2. COMPARISON OF MADISON AND ALBANY STUDIES

	Madison	Albany
Total number of babies	4,322	200
Proportion male	0.498	0.543
Total number of anomalies	646*	84 (105)
Mean number of anomalies per baby	0.149	0.420 (0.520)
Total number of babies with anomalies	609	67 (79)
Frequency of anomalous babies	0.141	0.335 (0.395)

* Calculated from Table 2 of the Madison study¹ assuming three defects in each of the two babies listed as having three or more defects.

Figures not in parentheses refer to those defects listed by the Madison study (Tables 3 and 4) which were found in this study. The number of anomalous babies, 67 in 200, is significantly different from the Madison total ($\chi^2 = 54$, $P < 0.001$). Totals in parentheses include those scored by the Madison study as well as Sydney lines, flat nasal bridges and hyperextensible thumbs.

The Poisson distribution tests the tendency of observed events to cluster. If the observations being scored occur independently and thus are the results of single hits by multiple causal events, then their distribution should agree with that predicted by the Poisson distribution. If they cluster, that is, are frequently the consequence of multiple hits by single causal events, then their distribution should deviate from the Poisson. Analysis of our data and those published after the earlier investigation reveals a close agreement with that predicted on the assumption of a single hit aetiology (Table 1). In spite of this the frequency of minor malformations was significantly higher in the Albany than in the Madison population, even when the three additional defects scored in the Albany study were excluded (Table 2). This may reflect (1) different ethnic and socio-economic structures of the populations studied; (2) differences in type and extent of teratological factors operating on the two populations, and/or (3) differences between the two studies in the diagnostic criteria for particular defects. This question is currently being investigated. It is interesting, however, that two studies carried out 6 years apart by different observers with different anomalies scored, populations studied and incidence of anomalies both revealed a Poisson

distribution. This strongly implies that the observations reflect a real human biological phenomenon.

There is one exception to the general conclusion. The Madison study apparently scored a unilateral malformation (such as a single simian line) with weight equal to a bilateral malformation. To facilitate comparison, we did the same with our own data. When we analysed individual malformations of paired structures, however, we found that if a defect was present in one of a paired structure it was more frequently present in the contralateral structure in the baby studied than in a baby chosen randomly (Table 3). This is also apparent from the Madison data in which both unilateral and bilateral incidences were presented. Thus minor malformations unassociated with major malformations do cluster, but only with regard to bilateral manifestation.

Table 3. UNILATERAL AND BILATERAL INCIDENCE OF DEFECTS ($\times 10^{-3}$)

	Madison			Albany		
	Unilateral	Unilateral ^{2*}	Bilateral	Unilateral	Unilateral ^{2*}	Bilateral
Lack of helical fold	28.9	0.84	6.2	50	2.5	25
Ear tags	0	0	2.3	26	0.6	0
Simian creases	26.6	0.70	16.7	40	1.6	30
Sydney lines	—	—	—	45	2.0	30
Clinodactyly	5.1	<0.1	4.9	5	<0.1	20
Epicanthal folds	0.9	0	3.2	5	<0.1	5

* The square of the unilateral incidence. The expected bilateral incidence assuming independence of lateral manifestation is twice the product of the incidence on either side. This cannot be calculated from the data in their present form but is less than the square of the total unilateral incidence which is given in this column. The bilateral incidences are greater than these latter figures in ten out of eleven cases in which the comparison can be made. By the sign test³ this is significant at at least the 5 per cent level.

These conclusions apply only to the malformations investigated. If we could investigate minor defects elsewhere in the body, such as variations in vascular supply and visceral anatomy, we might find that they were positively correlated with the occurrence of the more superficial anomalies studied. Furthermore, particular pairs of minor malformations may show a positive tendency to associate even though analysis of the distribution of all minor birth defects had no such general tendency. But many more data would be required adequately to investigate this question.

We thank Dr Alan MacCollam, Sister Jean McGinty and other members of the St Peter's Hospital Medical and nursing staff for their help.

In Vitro Conversion of DDT to DDD by the Intestinal Microflora of the Northern Anchovy, *Engraulis mordax*

THE tissues of many species of fish contain DDT and two of its derivatives, DDE and DDD. Fish which feed on plankton, such as the northern anchovy *Engraulis mordax*, acquire DDT residues primarily through the assimilation of food¹⁻³. The reductive dechlorination of DDT to DDE and DDD has been demonstrated in three species of salmonid fishes: Atlantic salmon^{4,5}, cutthroat trout⁶, and rainbow trout⁷. The purpose of this investigation

was to determine whether the intestinal microflora of the northern anchovy is capable of dechlorinating DDT and to elucidate the relative importance of bacteria and fungi in this process.

The intestinal contents of twenty-five adult anchovies were drained into a sterile test tube to which 15 ml. of sterile Difco nutrient broth was added. Aliquots (2 ml.) were injected into twenty sterile test tubes (24 ml. capacity) equipped with vaccine caps, and the cultures divided into four experimental groups: (i) series A was left unaltered; (ii) series B was inoculated with 100 units each of penicillin and streptomycin to suppress bacterial activity; (iii) series C was inoculated with 100 units of mycostatin to suppress fungal activity; and (iv) series D was inoculated with 100 units each of penicillin, streptomycin and mycostatin. One control was run with each series, in which nutrient broth was substituted for intestinal contents.

Each culture was inoculated with 0.05 ml. of 111 p.p.m. ¹⁴C-DDT ethanol solution and incubated anaerobically in a nitrogen atmosphere at 15° C in the dark for 6, 12, 24, 48 and 72 h. After digestion with a glacial acetic-perchloric acid mixture⁸, 4 ml. of water was added and the DDT residues extracted with 10 ml. of hexane and concentrated to 0.5 ml. in a Kuderna Danish evaporator. The DDT residues in 0.05 ml. of the concentrate were separated by descending chromatography using 2,2,4-trimethylpentane as the mobile solvent and 8 per cent 2-phenoxyethanol in anhydrous ethyl ether as the immobile solvent⁹. The chromatograms were cut into 1 cm horizontal strips and counted with a Nuclear Chicago Unilux II scintillation counter. The peaks were identified by parallel chromatography using 1/100 DDT, DDE and DDD standards and AgNO₃ as the chromogenic agent⁹.

After the extraction was completed, each culture was filtered through HA 'Millipore' filters, and the filter (particulate fraction) and filtrate (polar fraction) counted with the scintillation counter.

Table 1. Most activity was recovered in the hexane fraction (Table 1). No ¹⁴C-DDD or DDE appeared in the controls, and the activity found in the polar and particulate fractions was considerably less than in the test cultures. All the test cultures contained high concentrations of ¹⁴C-DDD, but little or no ¹⁴C-DDE. The highest levels of labelled DDD occurred in group A in which neither bacterial nor fungal activity was suppressed, and the lowest in group D where both were suppressed. Both

Fig. 1. Relative amount of labelled DDD (—○—) and polar fraction activity (---□---) recovered as a function of incubation time. Values were calculated after subtracting controls. Bacterial activity in group B (○) and fungal activity in group C (□) were inhibited.

fungi and bacteria converted DDT to DDD, and the efficacy of this conversion is shown by the high level of ^{14}C -DDD observed after only 6 h of incubation in group A. This rapid metabolism of DDT to DDD may have important consequences for survival because DDD is less toxic than DDT^{10,11}, and the degradation and assimilation of ingested food require several days¹².

A relatively large amount of labelled material remained in the cultures after the hexane extraction. From 18 to 53 per cent of the recovered activity was particle bound in groups A, B and C. Particle bound activity was only 6 to 18 per cent in group D where microbial activity was most inhibited. Polar phase activity was also lowest in group D where it constituted 0.6 to 1.6 per cent of the recovered activity as opposed to 0.7 to 4.0 per cent in groups A and B. This may indicate further metabolism of DDD to water soluble products such as DDA and the incorporation of labelled material into refractory organic compounds.

Some differential activity of the intestinal fungi and bacteria is suggested. In group B, where bacterial activity was suppressed, DDD levels were lower and polar phase activity higher than in group C where fungal activity was suppressed (Fig. 1). This indicates that while both bacteria and fungi metabolized DDT to DDD, the fungi were primarily responsible for further degrading DDD to a water soluble product in anaerobic conditions.

Effect of Iron on the Bactericidal Proteins from Rabbit Polymorphonuclear Leucocytes

WHILE investigating the bactericidal action of the basic proteins released from the lysosomes of rabbit polymorphonuclear leucocytes, we found that the rate of destruction of staphylococci was influenced by the medium in which the test was carried out. When a chemically defined medium¹ (containing phosphate buffer at pH 7.4, glucose, seventeen amino-acids, thiamine, nicotinamide and salts of Mg^{2+} , Mn^{2+} , Fe^{2+} or Fe^{3+}) was used, the bactericidal action of the leucocyte extracts was markedly inhibited and in certain cases abolished. The inhibition was due to the presence of Fe^{2+} or Fe^{3+} .

Two methods were used for obtaining extracts from the lysosomes of rabbit polymorphs: (1) treatment of whole leucocytes with staphylococcal leucocidin in the presence of Ca^{2+} (refs. 2 and 3); (2) acid extraction of the lysosomal fraction obtained by sucrose gradient ultracentrifugation⁴, followed by separation of the bactericidal basic proteins (GE)⁵ on a 'QAE-Sephadex' column (personal communication from A. Griffiths and A. C. Allison) and concentration either by freeze-drying or precipitation by $(\text{NH}_4)_2\text{SO}_4$. GE at a concentration of 0.02 mg/ml. was used in all the experiments described here.

The bactericidal activity of these extracts was tested by incubating well washed organisms from an overnight culture at 37° C in the chemically defined medium previously described, but omitting any metal salts. Fig. 1 shows the bactericidal action of GE on eight strains of staphylococci and its reversal by Fe^{2+} in a concentration of M/2,000 in M/1,500 sodium citrate. Sodium citrate alone had no effect. In some strains, the bactericidal action was completely reversed by Fe^{2+} , whereas in others it was only partially reversed. This difference was not related to the ability of the organism to produce coagulase. Fig. 2 shows a similar bactericidal action of GE on two strains of *B. anthracis*. Both strains, Sterne vaccine and the virulent M36, were sensitive to GE, and the effect was reversed by Fe^{2+} . Similar results were obtained with *Strep. faecalis*, *Listeria monocytogenes*, *Ps. aeruginosa* (Fig. 3) and *E. coli*. The latter two organisms not only survived but grew rapidly in the presence of GE when Fe^{2+} was present. Haematin containing an equivalent amount of Fe was even more effective than free Fe^{2+} .

There was a relationship between the concentration of GE used and that of Fe^{2+} required to overcome its bactericidal action, suggesting a reaction between Fe^{2+} and the basic proteins. This was confirmed by adding FeSO_4 to a neutral solution of GE, when a precipitate giving a strongly positive reaction for Fe^{2+} was formed. The precipitate was soluble at pH 2.0, and after dialysis overnight at this pH lost its reaction for Fe^{2+} , and remained soluble when the pH was raised to 7.0. The protein precipitated by Fe^{2+} contained a 5–10-fold greater bactericidal specific activity than the original GE, and the protein remaining in the supernatant was inactive. Fe^{2+} -precipitation has accordingly been used as a step in the purification of GE.

Fig. 1. The reversal by Fe^{2+} of the bactericidal action of basic proteins from rabbit polymorphs on staphylococci ($10^6/\text{ml.}$). Strains 1-4, 7, 8 coagulase positive; strains 5, 6 coagulase negative. —, Without Fe^{2+} ; ----, with $\text{M}/2,000 \text{ Fe}^{2+}$.

Although from these results it is clear that Fe^{2+} reacts with and inhibits the action of the bactericidal basic proteins from leucocytes, it may also inhibit other bactericidal proteins in leucocyte lysosomes. The effect of $\text{M}/2,000 \text{ Fe}^{2+}$ on the bactericidal action of lysozyme at a concentration of 0.02 mg/ml. was tested on a sensitive strain of *Staph. epidermidis* and shown to be negative. Fe^{2+} was also tested in the myeloperoxidase- H_2O_2 system^{6,7} in the conditions described by Klebanoff⁷ using *E. coli* and *Staph. epidermidis*. In neither case was the bactericidal action by $\text{M}/2,000 \text{ Fe}^{2+}$.

The effect of Fe in increasing the virulence of bacteria has received much attention⁸⁻¹¹. In a discussion of their observations on the effect of Fe in enhancing the virulence of *E. coli* and *Past. septica*, and in reversing the protective effect of antisera, Bullen and Rogers¹¹ interpret their results as due to a reversal of the bacteriostatic action of normal and immune serum by saturation of the serum transferrin with Fe. It is postulated that the combined effect of transferrin, β_2 and γ -globulin in the serum

interferes with the Fe metabolism of the organism, and the addition of Fe restores the balance.

Using mice injected intraperitoneally with a sublethal dose of *E. coli* with and without Fe^{2+} , we have confirmed the enhancing effect of Fe on virulence (Table 1). We have also demonstrated a profound effect of Fe^{2+} (Table 2) and haematin in enhancing the virulence of *Staph. aureus* and of Fe^{2+} in enhancing that of *B. anthracis*. These Gram positive organisms are not subject to the bacteriostatic or bactericidal action of antibody and complement. We have not been able to demonstrate a bactericidal or bacteriostatic action of normal rabbit serum on *Staph. aureus* or *Staph. epidermidis* provided the serum is

Fig. 2. The reversal by Fe^{2+} of the bactericidal action of basic proteins from rabbit polymorphs on *B. anthracis* (two strains). Conditions as in Fig. 1. Sterne strain: ■, GE alone; ●, GE + Fe. M36: □, GE alone; ○, GE + Fe.

2	12	M/1,400	10
3	12	M/2,800	8
4	12	0	0

10^7 washed cells of *E. coli* from an overnight culture were injected intraperitoneally with the stated concentration of FeSO_4 in equimolar sodium citrate.

Table 2. EFFECT OF Fe^{2+} ON THE VIRULENCE OF *Staph. aureus* IN MICE

Group	No. of mice	Concentration of Fe^{2+}	Deaths	Total deaths
			Day: 1 2 3 ... 14	
1	12	M/160	8 3 0 ... 0	11
2	12	M/320	4 1 0 ... 1	6
3	12	M/640	3 2 1 ... 0	6
4	12	0	0 0 0 ... 0	0

Conditions as in Table 1 using 10^8 washed cells of *Staph. aureus*.

obtained from clotted plasma¹². It therefore seems unlikely that the system described by Bullen and Rogers plays a part in increasing the virulence of these organisms. Although serum transferrin may not be concerned, however, Masson, Heremans and Schonne¹³ have recently reported the presence of the iron-binding protein lactoferrin in neutrophil leucocytes, which may act similarly. Masson, Heremans, Prignot and Wauters¹⁴ using lactoferrin from bronchial mucus showed that it was bacteriostatic for *Staph. epidermidis*.

A sample of apo-lactoferrin from human milk was tested for bactericidal action on staphylococci and for its reversal by Fe^{2+} in the same conditions as in our previous tests. A bactericidal action was obtained only when very large doses (1 mg/ml.) were used (Fig. 4), and the effect was not reversed by Fe^{2+} . It is therefore clear that the bactericidal action of GE is not attributable to lactoferrin.

Preliminary results from work on the intracellular killing of bacteria by whole polymorphs have shown that Fe^{2+} has a marked effect in protecting staphylococci from destruction, although phagocytosis is not affected by the concentration of Fe^{2+} used.

We thank Dr A. C. Allison, National Institute for Medical Research, for much helpful advice; Dr S. J. Klebanoff, US Public Health Service Hospital, Seattle,

for a sample of myeloperoxidase; Dr P. L. Masson, University of Louvain, for a sample of apo-lactoferrin; Dr A. M. Woodin for supplying rabbit polymorphs, and fractions of these containing lysosomes; and Mrs C. Dillon for technical assistance. The work was carried out with the help of a grant from the Medical Research Council.

Viable Algae in House Dust

HUMAN allergic reactions to algae have been documented¹, but so far these disorders have been recognized only after exposure to algae-infested waters. A number of investigators have suggested, however, that air-borne algae constitute a source of respiratory hypersensitivity reactions in susceptible individuals²⁻⁴. Viable cultures of algae were obtained from atmospheric samples by van Overeem in 1937⁵. More recently, Gregory *et al.*⁶, Schlichting⁷ and Brown *et al.*³ confirmed and extended these findings. Air-borne dissemination of algae was suspected as an explanation for the high incidence of positive skin reactions, reaginic antibodies, and positive provocative responses obtained in atopic patients tested with aqueous extracts of various species of green algae⁴. It seemed that one likely source of air-borne algae would be ordinary house dust and we now report the results of our investigation of this possibility.

Aliquots (0.1 g) of house dust collected from various indoor localities in Cincinnati, Ohio, between February and May 1969 were inoculated into two culture media: Bristol⁸ and modified Chu No. 10 (ref. 9). Viable algae were cultured from all the dust samples taken from forty-one homes. In these culture conditions the most frequently observed organisms were *Chlorella*, *Chlorococcum*, *Schizothrix*, *Planktosphaeria*, *Chlamydomonas*, and *Anabaena* (Table 1). Samples from three commercial producers of house dust allergenic extract also revealed viable algae (Table 2). In general, the algal organisms found in house dust used in the manufacture of commercial allergenic products belonged to the same genera that were frequently observed in dust cultures collected from individual homes.

Quantitative data were obtained for commercially derived dust samples by plating 0.01 g of dust, diluted in

<i>Dictyosphaeria</i>	1	<i>Palmelloccoccus</i>	3
<i>Fragilaria</i>	2	<i>Planktosphaeria</i>	16
<i>Gomposphaeria</i>	1	<i>Scenedesmus</i>	3
<i>Kentrosphaeria</i>	1	<i>Schizothrix</i>	21
<i>Microcoleus</i>	1	<i>Stichococcus</i>	3

Tris buffer, on Bristol and modified Chu No. 10 agar plates. These plates were prepared using a basal layer of 1.5 per cent agar which was overlaid with an inoculum layer of 0.5 per cent agar. The average algal counts per g for Purex, Center and Hollister-Stier Laboratories were 175, 240 and 1,250, respectively. (These represent minimal values for the competitive inhibition and colonization characteristics of many algae undoubtedly affect the efficiency of plating.) Allergenic extracts for human studies were prepared from organisms isolated from two homes and from a commercial sample supplied by Hollister-Stier Laboratories. *Chlorococcum* and *Chlorella* species were from home samples while a second *Chlorella* species was obtained from the commercial source. These members of the order Chlorococcales are commonly encountered in sampling for air, soil and water-borne algae⁴. All cultures were purified by repetitive subculturing on plates.

Table 2. COMPOSITE LIST OF ALGAE ISOLATED FROM HOUSE DUST USED IN MANUFACTURE OF COMMERCIAL ALLERGENIC PRODUCTS

Commercial source	Algae
Purex Co.	<i>Chlorella</i> <i>Anabaena</i>
Center Labs.	<i>Chlorococcum</i> <i>Stichococcus</i> <i>Schizothrix</i> <i>Chlorella</i>
Hollister-Stier Labs.	<i>Schizothrix</i> <i>Chlorella</i>

Eighty-four patients undergoing allergic evaluation for suspected respiratory allergy were first skin tested intracutaneously with 0.02 ml. of 1:10,000 dilutions of four commercial house dust extracts (Purex, Hollister-Stier, Center and Endo). Only reactions consisting of erythema and a circular weal measuring at least 0.5 cm in diameter were considered positive. If skin tests were negative at this dilution, patients were retested at 1:1,000 dilutions. Thirty-seven patients reacted to 1:10,000 dilutions of one or more of the commercial house dust extracts and forty-one patients showed positive reactions to 1:1,000 dilutions of one or more of the same extracts. At the same time skin tests were also performed with allergenic extracts prepared from the three house dust algal isolates. Of the thirty-seven patients who reacted to 1:10,000 dilutions of the various commercial house dust extracts, twenty-two displayed positive reactions to one or more of the algal extracts diluted 1:10,000 and five reacted to the same extracts diluted 1:1,000. In the group of forty-one patients who showed reactions to dust extracts diluted 1:1,000, only one reacted positively to a 1:10,000 dilution of the algal extracts whereas twenty-one reacted positively to algal extracts diluted 1:1,000. Most of the algal positive patients (70 per cent) reacted to all four dust extracts, the highest correlation (87 per cent) being observed in patients reacting to an extract prepared from the Hollister-Stier *Chlorella* isolate. Of the dust-positive patients who gave negative reactions to the algal extracts, only 35 per cent reacted to all four dust extracts. No skin reactivity could be elicited with any of the algal extracts in patients showing negative skin test responses to house dust extracts. This correlation was not attributed to lack of skin reactivity, for these patients gave positive reactions to other common allergens (fungi and pollens of ragweed, grass and trees).

Of the 84 patients tested, 58 per cent showed positive responses to one or more algal allergens, consistent with our previous results⁴. Cross reactivity between the algal allergens differed somewhat in this study, however. Previously⁴ no significant differences or similarities were observed between skin test reactivity of *Chlorella* and *Chlorococcum* allergens. Here we observed that 69 per cent of patients showing positive tests to the extracted *Chlorella* isolate from Hollister-Stier also reacted to the other two allergenic isolates, one of which was a *Chlorococcum* species.

House dust, a highly complex material with many known allergenic components¹⁰, also seems to be a likely source of human exposure and sensitization to many varieties of algae, which may give rise to clinical allergic problems.

We thank Miss Mary-Ellen Morris for technical assistance and Dr C. M. Palmer for the identification of algal isolates. We also thank Center, Hollister-Stier and Purex Laboratories for unprocessed dust samples.

Asymmetrical Distribution of the Potential Difference in the Toad Lens

THE electrical p.d. across the plasma membrane of cells may be either uniformly distributed around its surface or, as in composite epithelial membranes such as the amphibian skin and urinary bladder, asymmetrically distributed. In the former type of cell, ion transport takes place from the inside to the outside of the cell. In the latter, ions move between the bathing solutions across the entire cell.

An electrical p.d. of about 60 mV (negative inside the lens) has been measured between the inside of the amphibian lens and its external bathing medium¹⁻³. It has generally been assumed, but not proved, that this p.d. is uniformly distributed around the entire surface of the lens. This feature, together, with the high K⁺ and low Na⁺ and Cl⁻ concentration in the lens, has prompted the comparison with a giant cell⁴. The observations which we describe here indicate that this is not valid in the lens of the toad *Bufo marinus*.

We have measured the Na⁺, K⁺ and Cl⁻ content of the ocular fluids and the lens. The concentrations (mequiv/kg water) in the proportions vitreous : lens : aqueous are 111 : 31 : 117 for Na⁺; 3.8 : 82 : 2.3 for K⁺; 108 : 26 : 101 for Cl⁻ (means of ten). The ionic gradients across the toad lens thus conform to the usual pattern. Storage of the toad lens for 24 h at 5° C results in an accumulation of Na⁺ and Cl⁻ and a loss of K⁺. We have also immersed the isolated toad lens in modified Ringer solution⁵ and inserted a microelectrode (filled with 3 M KCl) in it through the capsular wall and found—as in the frog lens—an electrical p.d. of 59 ± 2.5 mV, with the outside surface positive.

Other experiments show, however, that this electrical p.d. is not uniformly distributed. This became apparent to us after carrying out two types of experiments. Initially we suspended the lens in a glass "cradle" con-

nected with rubber tubing to a reservoir filled with Ringer solution (Fig. 1a). The exposed face of the lens was kept moist by dripping Ringer solution. When Ringer agar bridges were placed so as to record the p.d. across the whole lens from both its surfaces, a mean electrical p.d. of 23 ± 1.7 mV was observed (anterior face positive).

The second method involved inserting the lens into a piece of glass tubing joined at each end to a chamber which contained circulating Ringer solution (Fig. 1b). When the lens was fixed in such a "divided chamber" an electrical p.d. of 25 ± 2.9 mV (anterior face positive) was recorded. The short circuit current (s.c.c.), amounted to 8 ± 0.8 μ A per 0.28 cm² cross-sectional area of the lens (28.5 μ A/cm²). The p.d. and s.c.c. were stable for several hours. In s.c.c. conditions, unidirectional fluxes of Na⁺ and Cl⁻ using ²²Na and ³⁶Cl were measured. Sodium fluxes were equivalent to: anterior to posterior 1.3 ± 0.4 μ A, posterior to anterior 2.4 ± 0.5 μ A; Cl fluxes: anterior to posterior 2.53 ± 0.16 μ A; posterior to anterior 2.28 ± 0.21 μ A. Clearly the net Na or Cl fluxes or both cannot explain the total s.c.c. Also, considering the high concentration of K⁺ in the lens and that the inside of the lens is negative with respect to both bathing solutions, it is very unlikely that an electrogenic K⁺ pump could be responsible for the p.d. and the s.c.c. It is possible that ions other than Na⁺, K⁺ or Cl⁻ are being actively transported across the whole lens, namely, H⁺ or HCO₃⁻; that a non-electrogenic Na⁺:K⁺ pump is maintaining the Na⁺ and K⁺ gradients or that organic ions are being produced inside the lens and a differential permeability between the anterior and posterior surfaces produces the p.d. across the whole lens.

Finally, another series of experiments were conducted to elucidate the contribution of each surface to the p.d. Microelectrodes were inserted laterally into the middle of a lens mounted in the "divided chamber" (Fig. 1b). In this way the p.d. across both the anterior and posterior surfaces could be individually studied, and the effect of ionic replacement, in either bathing solution, on each p.d. measured. The normal p.d. across the anterior surface was found to be 57 ± 4.2 mV whereas the p.d. across the posterior surface was 31 ± 3.8 mV (inside in both cases negative). The p.d. across the whole lens was 26 ± 2.3 mV.

Table 1. EFFECTS OF IONIC CHANGES ON THE p.d. ACROSS THE ANTERIOR AND POSTERIOR SIDES OF THE TOAD LENS

Bathing solution	Change in p.d. (mV)	
	Posterior	Anterior
Cl ⁻ -free posterior side	0	0
Cl ⁻ -free anterior side	0	+4
Na ⁺ -free posterior side	+6	0
Na ⁺ -free anterior side	0	-7
K ⁺ , 75; Na ⁺ , 31; Cl ⁻ , 33 posterior side (mequiv/l.)	-6	0
K ⁺ , 75; Na ⁺ , 31; Cl ⁻ , 33 anterior side (mequiv/l.)	-7	-27

The p.d. on the two sides of the lens behaved differently when the ionic compositions of their bathing solutions were altered (Table 1). Omission of Cl⁻ had little effect. Na⁺-free media caused a small decline in p.d. at the anterior face and a similar increase at the posterior side. Elevation of K⁺ caused a rapid decline of the p.d. at the anterior side to a stable value of 20 mV but had little effect posteriorly. All the changes were reversible and the individual effects on each side were added when ionic changes were made simultaneously in both solutions.

These results clearly indicate that (a) the lens is not a symmetrical organ but a polarized one, the electrical

Fig. 1. a, "Cradle" system for supporting the toad lens *in vitro*; b, "divided chamber" system for studying the electrical properties and permeability of each side of the lens. The p.d. and s.c.c. are recorded from Ringer-agar bridges inserted through the ports in each chamber. A microelectrode can be inserted through a small hole in the tubing connecting the two chambers and into the lens so that recordings of the p.d. can be made across each side of the tissue.

properties of its anterior and posterior surfaces being different; (b) Cl⁻ is relatively unimportant for the maintenance of p.d. at either surface; (c) removal of Na⁺ has an opposite effect on each surface suggesting that Na⁺ is necessary in the anterior bathing solution for the maintenance of at least part of the p.d. Its effect on the anterior side is opposite to what we would expect if Na⁺ moves at that level only by diffusion; (d) the anterior surface is more sensitive to depolarization by K⁺ than the posterior.

Our results suggest that at least partially the ionic gradients and the p.d. found between the lens and surrounding humours are the result of the operation of a Na⁺ pump located at the anterior surface level that moves Na⁺ from inside the lens to the outside solution. The entire lens is surrounded by a capsule. Underneath the capsule—on the anterior side only—a single layer of epithelial cells is present. It seems likely that these cells contribute to the asymmetrical electrical properties of the lens.

We thank Dr Andrew Ferry for preparing sections of the toad lens. This work was supported by grants from the National Society for the Prevention of Blindness (to O. A. C.), the US National Science Foundation (to P. J. B.), the Hartford Foundation (to H. T.) and the US National Institutes of Health (to C. D. M.).

Role of the Perineural Sheath of Peripheral Nerve on Fluxes of L-Glutamate *in vitro*

THE possibility that L-glutamate might be the excitatory transmitter released by the central terminals of sensory afferent fibres has prompted some studies on its release in peripheral nerves^{1,2}, but there have been no systematic studies of the resting fluxes of glutamate and it is not known whether the perineural sheath is a barrier to the movements of this substance.

Short segments of sheathed and desheathed frog (*Rana catesbiana*) sciatic nerves or "bags" made from isolated sheaths were used in this study. For studying fluxes in whole nerves, uniformly ¹⁴C-labelled L-glutamic acid (188 mCi/mmol, New England Nuclear Corp.) was added to the frog Ringer solution to give a final concentration of 22 μ M, 4.08 μ Ci/ml., and for studies on isolated sheaths the concentrations of tracer substances were: ¹⁴C-glutamate, 5.4 μ M; ¹⁴C-sucrose, 1.011 mM (135 mCi/mmol, Calbiochem); ³HOH, 75 mM (25 mCi/g, New England Nuclear Corp.); ³⁶Cl⁻, 3.6 mM (10.2 mCi/g, as NaCl, Radiochemical Centre, Amersham). Radioactivity was monitored by liquid scintillation counting and metabolism was checked using column or paper chromatography. To study the initial influxes, nerves were incubated in radioactive medium at 4°, 17° and 22° C for periods of 30 s to 30 min and to characterize the "loading process" (for

nerves used in efflux studies) nerves were soaked for longer periods.

A very rapid exponential accumulation of glutamate occurred within the first 5 min of immersion in the active medium, presumably because of diffusion, which was followed by a constant rate of influx for the next 25 min. The mean values for three to six nerves (for each point) were plotted for the influx which occurred at 5, 10 and 30 min and regression lines were calculated for these points by a method of least squares. Influxes (M_1) were calculated using a modification of the equation of Keynes³, according

to which, $M_1 = \frac{dY_1}{dt} \cdot \frac{C_0}{Y_0}$, where $\frac{Y_0}{C_0}$ is the external specific

radioactivity and $\frac{dY_1}{dt}$ is the regression coefficient (slope),

and were found to be 2.6, 3.7 and 5.9 pmoles/g.s in desheathed, and 1.6, 1.4 and 0.7 pmoles/g.s in sheathed nerves at 4°, 17° and 22° C, respectively. This indicates that the sheath is indeed a barrier to this temperature-dependent process.

In Fig. 1 are shown representative plots of the rates of efflux of ¹⁴C from sheathed and desheathed companion nerves at 22° C after these had been soaked in labelled medium for 19 h at 4° C. By calculating "apparent" diffusion coefficients⁴ (data not shown) and rate constants (Table 1) from these plots, it became evident that an effect of the sheath on the efflux of glutamate could not be shown by this method; the reasons for this are likely to be related to the adsorption of labelled medium to the sheath itself and to the catabolism of glutamate by the nerves. With the "bags" made from inverted nerve sheaths which were filled with Ringer solutions containing labelled substances, however, the above-mentioned difficulties were overcome, that is, a negligible catabolism of glutamate occurred, for there were no cells or axons present and there was no radioactive medium present on the outer surface of the sheath. Table 2 shows that with this method the sheath can also be shown to be a barrier to the outward diffusion of glutamate.

From these results, it is clear that the sheath is indeed a barrier to the fluxes of glutamate, but that this effect cannot be shown in whole nerves because serious errors arise from the adsorption and catabolism of glutamate.

I thank Professor K. Krnjević for helpful discussions about this work, which was supported by the Canadian Medical Research Council.

Odour Discrimination: "Sex Pheromone Specialists" in the Olfactory Lobe of the Cockroach

THERE has been widespread interest in the natural sex attractant of the American cockroach, *Periplaneta americana* (L.), although its structure is unknown¹⁻⁵. The recording of the summated receptor potentials (electro-antennogram) from the *Periplaneta* showed that the sex pheromone elicited electrical responses not only in the antennae of the male but also in those of the female⁶. We have tested the responses in the olfactory centre with single units recording in the lobe, and proved that specialized neurones for the prepurified sex pheromone do exist in the olfactory lobe of both sexes.

The materials, operative procedures and recording system used in the present experiments were the same as those described earlier^{7,8}. Quantitative stimulation was brought about by a current of air passing over a piece of filter paper which was impregnated with a known amount of the substance to be tested. The substance was mounted in a small glass bottle on the air flow system in such a way that it could be easily exchanged. The prepurified sex pheromone used was extracted by the same procedure as in the previous experiment⁸.

Fig. 1 shows an example of the single cell (unit) responses of the adult male cockroach to the prepurified sex pheromone. The greater the concentration, the higher the frequency of impulses accompanying the negative slow potential which might be well explained in terms of the excitatory postsynaptic potential of the synaptic membrane. This unit also occasionally responded with a weak increase of impulse discharge to several other compounds such as cycloheptanone, cyclopentanone, geraniol, ethylene glycol, methyl ethyl ketone, *trans*-2-hexenol, acetic acid and acetone. Creosote and clove oil occasionally elicit

Fig. 1. The discharge of impulses of the sex pheromone specific neurone from the olfactory lobe in response to a series of papers holding prepurified sex pheromone of increasing concentration (from B to F). Before stimulation in A (control), a rectangular calibration pulse of 0.5 mV (positive with reference to the ground) was applied. Film speed, 5 cm/s. Recording was made with a longer time constant (0.3 s).

Fig. 2. Impulse frequency at different concentrations of prepurified sex pheromone (●-●), methyl ethyl ketone (○-○), cycloheptanone (●-○), and *n*-butyric acid (●-○) during the first second of response. The curve (●-●) is the mean value of nine measurements of three units in each three individuals. The other three curves represent the impulse number of one measurement of the same unit demonstrated in Fig. 1. 0 in the abscissa denotes the original concentration of each compound; -1, -2, -3, -4 and -5 denote the 10, 100, 1,000, 10,000 and 100,000-fold dilution of the original concentration, respectively; C is control (air without odour).

weak inhibition of the spontaneous discharge of this neurone. On the other hand, the unit failed to respond to twenty-eight other compounds tested.

The reaction spectra among these units found so far showed considerable overlap or exactly the same spectra for a great variety of compounds. Some are responsive only to the prepurified sex pheromone. All, however, showed very great sensitivity to the prepurified sex pheromone, compared with other effective compounds as shown in Fig. 2. We should therefore like to call these cells which respond specifically to the sex pheromone the "sex pheromone specialists".

Whether the *Periplaneta* actually uses these particular neurones (sex pheromone specialists) to inform the higher centre of the sex pheromone remains to be seen, however, because females of this species also have the particular neurones ("sex pheromone specialists") which showed great specificity and sensitivity to the prepurified sex pheromone produced by other females of the same species.

We thank Drs T. Tamura, K. Iyatomi and T. Saito of Nagoya University for their encouragement and advice.

Tentacle Responses of the Sea Anemone *Anthopleura xanthogrammica* to Ultraviolet and Visible Radiations

WE have observed that exposure of anemones to ultraviolet and visible radiations can elicit two specific responses, flexion and retraction of the tentacles. A detailed investigation revealed that these responses were readily differentiated by their spectral region of maximum sensitivity.

The sea anemone *Anthopleura xanthogrammica* was adapted to the dark for 1 h and exposed at the oral disk to determine the responses of tentacles to several wavelengths from 240 nm to 600 nm at various dose rates and exposure durations. Radiations were incident at the surface of the test organism in a field size of approximately 1.75 cm by 2.5 cm. Background illumination of the anemone by a low-level red light made it possible for a dark-adapted observer to carry out the observations.

A Bausch and Lomb high-intensity diffraction grating monochromator, with a 150 W high pressure xenon arc lamp system, provided radiations at the specified wavelengths. Separate diffraction gratings, an ultraviolet (2,700 grooves/mm) grating and a visible (1,350 grooves/mm) grating were used for the spectral regions to increase resolution. The dose rate at each wavelength was measured with a YSI-Kettering radiometer equipped with a special collecting cone. Bimetallix quartz-bonded interference filters of neutral density were used to change the dose rate over several log units.

Because the same dose rate was not attainable at all wavelengths, it was necessary, in a few instances, to adjust both dose rate and exposure duration to achieve a specific radiation dose. This was done only if prior tests of the exposure variables showed that a reciprocal relationship existed between dose rate and exposure duration for evoking the response. Using the ultraviolet spectral grating, responses were tested over the wavelength range of 248–400 nm at dose rates ranging from 0.09×10^3 erg/cm²/s to 2.99×10^3 erg/cm²/s. With the visible spectral grating, responses were tested over the wavelength range from 350–600 nm at dose rates from 0.12×10^3 erg/cm²/s to 27.2×10^3 erg/cm²/s.

It was found that exposure to wavelengths of 340–600 nm induced a flexion of tentacles, without reduction in length and with the point of flexure near the base of the tentacle. In flexion, the extended tentacle changed its relationship to the oral disk from a nearly perpendicular position to a horizontal one. Flexion was always toward the rim of the oral disk and was independent of the direction of the incident radiation beam.

Radiations of 248–400 nm induced a retraction of tentacles. During retraction, the tentacles withdrew from their normally extended position and showed constriction of the apical and mesial tentacle regions. Both flexion and retraction responses were observed among tentacles exposed in the spectral region of 340–400 nm, but were still distinguishable as two separate responses.

The minimum effective (threshold) dose (ED) for each response at each wavelength was determined by more than sixty tests performed on twenty-eight anemones, so that the relative efficiency of the wavelengths used could be compared in an action spectrum. For tentacle flexion a series of test exposures, in which the dose was changed by small increments, was made around the oral disk of each anemone. The threshold (ED) was designated as the average between a dose causing flexion and the next lower dose increment that failed to produce flexion. In the case of retraction, the duration of continuous exposure, required to elicit retraction at a given dose rate, was specified as the effective dose. This was more convenient because the low dose rates available in the

ultraviolet region meant that much longer exposures were needed.

Action spectra for flexion and retraction were based on the relative efficiency of a wavelength in producing a response as compared with a reference wavelength. This is a modification of the method outlined by Jagger¹ to measure inactivation cross-sections. The relative efficiency was calculated from the formula

$$\text{ED (reference wavelength)} \times \frac{\text{nm (test wavelength)}}{\text{nm (reference wavelength)}}$$

The action spectrum for tentacle flexion (Fig. 1), derived from relative efficiency data, shows us that radiation at 500 nm is most efficient in producing a flexion response, and that the efficiency falls off rapidly to one-third at 450 nm and one-quarter at 400 nm and 550 nm. In the ultraviolet range, the efficiency increases from 400 nm to 360 nm, and decreases rapidly below 360 nm. No tentacle flexion was observed at wavelengths below 340 nm, even at high dose rates. Experiments by North and Pantin² on bending responses of the column of *Metridium* showed a similar maximum sensitivity to light at about 490–520 nm, but no peak of sensitivity at 360 nm.

Fig. 2 indicates that there is nearly uniform low effectiveness in producing retraction in *Anthopleura xanthogrammica* by radiation of 400–320 nm. A sharp rise in efficiency occurs below 320 nm with a peak at 280 nm, declining rapidly to less than one-quarter at 248 nm.

With respect to the distribution of reacting tentacles, those of the two inner cycles showed less sensitivity to visible radiations than tentacles of the outer cycles. At 450 nm, 7 per cent of the central tentacles and 88 per cent of the peripheral tentacles responded by flexion, while at 500 nm the percentages were 8 per cent and 90 per cent respectively. The more centrally located tentacles, however, showed little difference in retraction response from peripheral tentacles when exposed to ultraviolet radiations at 280 and 360 nm.

An analysis of the photic responses of *Anthopleura xanthogrammica* indicates that sensitivity is greatest for areas of most abundant sensory and nervous elements³. Tentacle flexion (Fig. 1) might be interpreted tentatively as a reaction mediated by photosensitive cells, whether they be specialized sensory cells or epithelio-muscular cells. So far, however, no specific photoreceptors or their pigments have been identified in the anemones.

The retraction response, with a maximum sensitivity at 280 nm, suggests absorption of radiation by substances

Fig. 1. An action spectrum derived for tentacle flexion in *Anthopleura xanthogrammica*.

Fig. 2. An action spectrum derived for tentacle retraction in *Anthopleura xanthogrammica*.

other than typical receptor pigments, perhaps by proteins and nucleic acids. While certain insects with highly organized photoreceptor systems have been found to have a well defined response to the ultraviolet region of the spectrum⁴ and to ionizing radiation⁵, the present study seems to be the first identification of behavioural reactions to electromagnetic radiations in the ultraviolet spectral range in the phylum below the arthropods.

Micro-injection of ¹⁴C-Sucrose into Single Living Sieve Tubes of *Heracleum*

We have made use of micro-cannulation—a new and potentially useful technique for plant physiology—by inserting glass micropipettes of 2–4 μ m tip diameter into mature living sieve tubes of *Heracleum sphondylium*. We used a micromanipulator¹ under a microscope with a Zeiss $\times 40$ water immersion objective. The technique in its present state of development may disturb the sieve element and so alter normal translocation, but it has potential advantages over the use of aphid stylets^{2,3}, for the glass is impermeable to water, the tips can be located precisely *in situ* and injection of solutes as well as withdrawal of sap are possible.

Our method was made possible by the direct observation of dancing "marker" particles which characterize functioning sieve tubes in *Heracleum*⁴. A strand of phloem 0.5 mm in diameter was isolated from xylem and parenchyma so that the strand was left attached to the plant at each end, but displaced from the living petiole. We located a suitable sieve tube under the microscope and inserted the micropipette so that the glass tip could clearly be seen in

the lumen in relation to sieve plates and marker particles. If the particles remained in the lumen near the glass tip, sparse in number and vigorous in action, damage was assumed to be minimal⁴. Because the sieve tube was under pressure, sap would usually force its way through an empty micropipette. For micro-injection we used a hydraulic system of mineral oil with the micropipette tip filled with tracer solution. The tip was inserted in the selected sieve tube, the solution was injected for 10–15 s, the tip was withdrawn and the strand was left intact for a given number of seconds. The strand was then excised at each side of the coverglass and at the basal and apical junctions with the petiole. Basal and apical sections were frozen on a sheet of solid CO₂ and further excised into sections 1–2 cm long. The tracer in each section was counted in a scintillation spectrometer for total periods exceeding 25 min. Counts were corrected for quenching and background.

In the first experiments, 0.2–0.5 μ l. of 0.3 M ¹⁴C-sucrose containing about 10⁴ d.p.m. were injected. After 5 min less than 1/100 of the radioactivity was detected within 8 cm of the origin in either direction. Most of it had disappeared. A sensitive Geiger counter placed 6 cm downstream from the microscope, however, registered several pulses of twice background in the first 2 min after injection. We therefore reduced the time between injection and excision and lengthened the isolated strand; ¹⁴C was then recovered both upstream and down, but localized in discrete sections of the strand—the shorter the time, the closer to the micropipette. Apparently injection induced a movement of sucrose in both directions away from the origin at 250–450 cm h⁻¹.

About twenty-five short-time injection experiments have been carried out so far during two summers. In twenty of these we have recovered peaks of tracer localized at rather irregular intervals with almost no counts in between (Figs. 1 and 2) and usually in both directions from the origin. To reduce possible damage in a sieve element due to injection pressure we have used as little as 2.0 $\times 10^{-3}$ μ l. (equivalent to a 6 mm length of tube containing perhaps twenty sieve elements). We still obtained tracer pulses with small injections and the distance moved in 2 min was about the same as with larger amounts. To see whether the first injection pulse had damaged the transport mechanism we have injected two 10 s pulses 60 s apart. Fig. 2B shows the result of such an experiment: the second pulse also appeared to move as readily as the first. We have also injected ⁴²KCl mixed with the

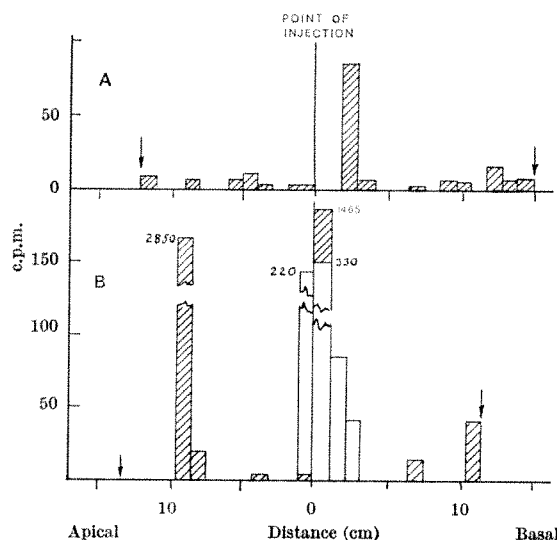

Fig. 1. Histogram showing the distribution of ¹⁴C-sucrose (hatched columns) and ⁴²K (white columns) along phloem strands of *Heracleum* 2 min after injection into a single sieve tube. Counts per minute are shown only when significantly different from background; patterns of distribution are not unusual. A, Single injection of 7 $\times 10^{-3}$ μ l., single isotope; B, single injection of 3 $\times 10^{-3}$ μ l., double isotope.

^{14}C -sucrose to see whether ^{42}K and ^{14}C travel together: as in Figs. 1B and 2B they do not seem to do so (five experiments). We have injected fluorescent dye into a sieve tube to investigate whether the dye moved in one or more sieve tubes: it seemed to move bidirectionally in a single sieve tube without appreciable lateral spreading in the first minute after injection. We have withdrawn samples from the sieve tube lumen for electron microscope study: they contain strands about 60–190 Å diameter, presumably of protein microfilaments⁵.

We have investigated the question of whether the strands we prepared can transport sucrose without injection. Dissected strands were allowed to touch a small drop of ^{14}C -sucrose + tritiated water (^3HHO) for 2 or 3 min and then excised, frozen and sectioned as before. The tracer travelled considerably further in 3 min (Fig. 3) than in 2 min. Clearly the tracer moved rapidly outward from the origin in both directions with the log c.p.m.—distance profile usually found in petioles⁶. But several types of tracer movement are evident: slow, medium and fast pulses of tracer were found in both directions to a distance from the origin which suggested speeds of 400 cm h^{-1} upwards and 280–400 cm h^{-1} downwards. In this type of experiment tracer must first be loaded into the translocation path before transport: a random loading plus transport would then give the results we obtained, but the front of the movement may indicate the distribution sum of pulse-like movements in or on individual sieve tubes. The distances traversed by the leading pulses in this experiment were similar to those from injection experiments lasting the same time. We conclude that in the displaced strands a bidirectional sucrose transport mechanism operates when the centre is the source.

The failure of ^{42}K to move far from the point of micro-injection is surprising, for it is well known that K is in the phloem sap³ and can be transported. One possibility is that the movement of K was prevented by a partial (Fig. 1B) or complete (Fig. 2B) blocking of mass flow by slime plugs at sieve plates, while transport of ^{14}C continued by an alternate mechanism. We suggest that sucrose travels on or within the microfilaments which, we think, normally traverses both sieve tube lumen and the plate pores. Thus if pressure surges from injection or strand excision causes the microfilaments to snap and form slime, irregular accumulations of ^{14}C would result. But whenever the disruption of microfilaments is not great, we suggest that sucrose is loaded onto this protenacious material and conducted in waves past sieve plates. We think that gentle injection tends to give wider bands of ^{14}C (Figs. 1A and 2A) than does high pressure injection

Fig. 3. Tracer profiles along an isolated phloem strand of *Heracleum* 3 min after the application of 0.3 M ^{14}C -sucrose in ^3HHO . Note the two different slopes to the log c.p.m.—distance profiles and the tracer pulses at 20 cm, apical and basal. The isotopes were counted together in this experiment because of the degree of local quenching of ^{14}C .

(Figs. 1B and 2B), but attribute the separation of tracers and irregularities to the slime plugging as against any loading-conducting properties of the microfilaments. Alternatively, the tracers might have been conducted through intercellular spaces.

We conclude that micro-injection into a single sieve tube is feasible. In our system we find evidence that two translocation mechanisms operate together, a slow mass flow for K and a much faster one for sucrose involving waves or pulses.

Effects of Inhibitors on Light-stimulated Synthesis in Radish Hypocotyl

THE effects of the inhibitors, D-threo-chloramphenicol and cycloheximide, on protein synthesis have been studied in several systems. In tissues of green plants, differential effects have been thought to be due to a preferential inhibition by chloramphenicol of protein synthesis mediated by 70S ribosomes as found in chloroplasts, while cycloheximide inhibits syntheses mediated by 80S cytoplasmic ribosomes¹⁻³ to a greater extent. We wish to report the effects of the two inhibitors on light-stimulated formation of anthocyanins and chlorophyll and on protein composition during the growth of excised radish hypocotyls.

Radish seeds (variety 'White Icicle') were germinated in the dark at 25° C for 48 h. The roots were carefully excised at the limit of the root hair zone and the testas were removed. The hypocotyls, with cotyledons attached, were incubated in distilled water (ten hypocotyls/10 ml.) and shaken continuously (100 cycles/min) at 25° C in either complete darkness or light (800 foot candles). In these conditions, the length of a hypocotyl increases consider-

ably from 5 to 21 mm (dark) or to 10 mm (light) in 48 h, entirely as a result of cell expansion.

Fig. 1 shows that cycloheximide, in a concentration greater than 10^{-7} g/ml., clearly inhibited anthocyanin synthesis to a greater extent than it affects chlorophyll formation, which is only markedly reduced by 2×10^{-6} g/ml. Chloramphenicol similarly inhibited the synthesis of both pigments in concentrations of 10^{-6} g/ml., but chlorophyll formation in the light was much more sensitive to this inhibitor— 3×10^{-6} g/ml. caused 50 per cent inhibition, while it required 3×10^{-5} g/ml. to have the same effect on anthocyanin formation.

A young radish hypocotyl contains considerable protein reserves, in the form of protein bodies, which disappear during growth, the total protein content of the hypocotyl remaining unchanged. The densitometer tracings in Fig. 2 show that proteins from unexpanded hypocotyls ("0 h" after germination for 48 h) contain a major component of mobility (relative to the mobility of the tracker dye—bromophenol blue) of 0.145. There are also some minor components of lower mobility and a diffuse series of components with a mobility of 0.15–0.60. During growth in the light for 48 h the protein component of mobility 0.145 (reserve protein) decreases in quantity; while a new sharply defined component of mobility 0.09 appears, and there is a general increase in the quantity of the protein components of mobility 0.15–0.60. The sharply defined band of mobility 0.09 has the same mobility as fraction I protein obtained from rapidly isolated radish chloroplasts, and a measurable quantity is only formed during growth in the light. Table 1 shows that the inhibitors were remarkably selective in our experiments, chlor-

Fig. 1. Effect of D-threo-chloramphenicol (a) and cycloheximide (b) on the formation of anthocyanin (■, extracted with 1 per cent HCl in methanol, A_{540} nm) and chlorophyll a + b (□, extracted with 80 per cent acetone⁴).

Fig. 2. Densitometer tracings of acrylamide gels stained with Coomassie blue, showing distribution of soluble proteins from hypocotyls cultured in the light for (a) 0 h; (b) 48 h in water of 50 μg/ml. of L-threo-chloramphenicol; (c) 48 h in 50 μg/ml. of D-threo-chloramphenicol; (d) 48 h in 2 μg/ml. of cycloheximide. Proteins were obtained by grinding hypocotyls in two volumes of 50 mM Tris; 0.2 mM EDTA; 10 mM MgCl₂; 5 mM reduced glutathione; filtering through nylon mesh (56 μm apertures; centrifuging at 102,600g, and subjecting the supernatant to electrophoresis on vertical slabs of 7.5 per cent polyacrylamide, pH 8.9 (ref. 6).

amphenicol completely inhibiting the formation of the protein component with a mobility of 0.09. Furthermore, this effect was only produced by the D-isomer; L-threo-chloramphenicol had no effect on the light-stimulated synthesis of fraction I protein, or on the synthesis of chlorophyll in hypocotyls or cotyledons grown in the light. This is a much clearer distinction between the D and L-isomer than that shown by MacDonald *et al.*⁵. Cycloheximide had little effect on the quantities of protein in the slow-moving bands, but caused a 25 per cent inhibition of the broad series of proteins of mobility 0.15–0.60.

These results confirm earlier reports that 1 mg/ml. of chloramphenicol inhibited the light-stimulated formation of chloroplast enzymes in *Euglena*, while cycloheximide had a smaller but variable effect³. Ingle⁷ found similar inhibitory effects of both cycloheximide (0.5–1.0 μg/ml.) and chloramphenicol (100–1,000 μg/ml.) on RNA synthesis in radish cotyledons during greening in the light, but a less clear cut difference in the effect of cycloheximide on the synthesis of chloroplast and cytoplasmic ribosomal RNA. During growth of the exised hypocotyl, no uptake of nutrients is required and a selective effect on uptake

Table 1. EFFECTS OF INHIBITORS ON FORMATION OF PROTEIN

* Data obtained from areas under peaks on densitometer tracing.

due to interference with oxidative phosphorylation is unlikely to be involved. There is no evidence of uncoupling of oxidative phosphorylation by these inhibitors in this tissue, the effect on oxygen uptake being extremely slight. The continued use of chloramphenicol in concentrations of about 50 µg/ml. in an attempt to eliminate or reduce bacterial contamination in metabolic studies using plant tissues is clearly inadvisable, unless it is known that the inhibitor has no effect on tissue metabolism, particularly RNA and protein synthesis.

Fixation of New Mutants

THE concept of permanent, inherited changes in proteins being brought about by the random fixation of neutral mutations has been advocated^{1,2} and criticized³ under the inappropriate heading of non-Darwinian evolution, a name better kept for other more general uses⁴.

Much of the discussion has depended on a simple result pointed out by Kimura⁵. In a population of N individuals, the chance of fixation of a new neutral mutation is $1/2N$. If the rate of mutation to such neutral variants is u per locus per gamete per generation, then if there are m loci in the population, the mean number of neutral mutants fixed per generation is $2Nmu$. $1/2N = mu$. That is, the rate per generation of fixation of neutral mutations is equal to their rate of production per gamete.

Kimura^{5,6} and King and Jukes¹ have derived rates of amino-acid substitution in proteins of approximately 18.4×10^{-10} changes per residue per year for eutherian mammals. From this, by making assumptions about the amount of mammalian DNA which is involved in structural genes, and about the average generation time in mammals, one can obtain a value as high as two neutral mutations fixed in any mammalian population in any generation. King and Jukes¹ have criticized Kimura's derivation of this value on the grounds that if all 4×10^9 base pairs of DNA in the haploid mammalian genome were involved in coding for polypeptides, there would be about 10^6 loci, and clearly with a mutation rate to lethals of 10^5 per locus, this means that an enormous number of lethal mutations must be occurring. It does not seem to have been noticed that an argument akin to Kimura's, cited earlier, leads to the conclusion that very large numbers of deleterious mutants must be fixed in each generation, if population size is small enough. It is well known^{7,8} that the chance of fixation of a new mutant with an advantage of s relative to the mean is

$$p_1 = \frac{1 - e^{-2s}}{1 - e^{-4Ns}}$$

and for a mutant with a relative disadvantage of t , the chance of fixation is

$$p_2 = \frac{e^{2t} - 1}{e^{4Nt} - 1}$$

Accordingly, with m loci and mutation rates u_1 and u_2 to appropriate alleles, the mean numbers fixed will be $2Nu_1mp_1$ and $2Nu_2mp_2$. Table 1 shows numerical values for the three cases. The value 10^{-5} was chosen for u as being of the generally accepted order of magnitude for deleterious mutation rates, and the values 10^{-6} and 10^{-7} were chosen as rates for neutral and advantageous mutations because these are clearly less likely events.

Table 1. MEAN NUMBERS OF MUTANTS FIXED PER GENERATION IN A POPULATION OF N INDIVIDUALS WITH MUTATION RATE u TO ALLELES WITH A SELECTIVE ADVANTAGE (OR DISADVANTAGE) OF s

N	m	There are m loci in the haploid genome			Mean number of mutants fixed per generation
		u	s		
100	10^4	10^{-5}	-0.001		0.081
		10^{-5}	-0.01		0.007
		10^{-6}	0.0		0.010
		10^{-7}	0.01		0.004
	10^6	10^{-5}	-0.001		8.141
		10^{-5}	-0.01		0.754
		10^{-6}	0.0		1.000
		10^{-7}	0.01		0.403
1,000	10^4	10^{-5}	-0.001		0.007
		10^{-5}	-0.01		0.000
		10^{-6}	0.0		0.010
		10^{-7}	0.01		0.040
	10^6	10^{-5}	-0.001		0.747
		10^{-5}	-0.01		0.000
		10^{-6}	0.0		1.000
		10^{-7}	0.01		3.960

This argument seems to suggest that small population size allows a greater rate of chance fixation of deleterious alleles than Haldane⁹ and Kimura and Crow¹⁰ felt possible for advantageous alleles. The result for advantageous alleles is even more extreme. Sved¹¹ and others¹²⁻¹⁴ have, however, shown that high rates of fixation of advantageous alleles are possible, given different assumptions about the mode of action of natural selection, so that it does seem likely that, as Richmond³ and Clarke¹⁵ have concluded, the reality of "non-Darwinian evolution" has yet to be demonstrated.

I thank Professor Alan Robertson and Dr B. C. Clarke for discussion.

Lee Wave Hypothesis for the Initial Pattern of Spread during the 1967-68 Foot and Mouth Epizootic

THE extensive and explosive initial spread of the 1967-68 foot and mouth disease epizootic in the English Midlands has been a subject of much speculation¹⁻⁴. After the first

outbreak was confirmed at Bryn farm on October 25 (day 1), some fifty-nine further outbreaks were confirmed between days 4 and 10 in a fan shaped area stretching north-east towards Chester, a distance of 56 km (see Fig. 1). The Ministry of Agriculture has argued that, because no human or mechanical links could be established between Bryn farm and subsequent outbreaks, many of these outbreaks were probably caused by the imported frozen lamb that was thought to be responsible for the Bryn farm outbreak¹. The only evidence for the view of the Ministry was that the lamb had been distributed near some of the outbreaks, and because the lamb had also been distributed extensively in other parts of England and Wales since August it seems very unlikely that many outbreaks should suddenly occur within a specific area and that they should occur approximately one incubation period after the Bryn farm outbreak.

Fig. 1 illustrates an alternative argument that Bryn farm (or Bryn farm together with neighbouring farms that might have been emitting virus at the same time) could have been the sole source and that most of the subsequent outbreaks were the result of airborne spread from Bryn farm. While the possibility of airborne spread has been confirmed for other periods during this epizootic and for other epizootics²⁻⁴, my attempts to model the spread of the disease⁴ have shown that the magnitude of the initial long range spread was far greater than in any other instance of long range spread during the remainder of the epizootic. Hence, if airborne spread was responsible for initial spread in the 1967-68 epizootic, then it was operating in a dangerously efficient manner.

Subsequent investigation revealed three curious features of the spatial pattern of initial outbreaks: the clustering of the outbreaks into three distinct clusters (see Fig. 1); the regular spacing of these clusters at 18-20 km intervals; and the fact that outbreaks in the downwind clusters occurred within the time of one incubation period after the Bryn farm outbreak. These features suggested that an atmospheric phenomenon known as lee waves may have helped the initial spread. Here I attempt to illustrate how this could have happened.

Bryn farm is located at the base of a valley ridge beside the Cheshire Plain. From October 15 to 26 the wind blew from the south-west at approximately right angles to this ridge. Fig. 2, a profile drawn through Bryn farm at an azimuth of 215°, makes these relationships clear. Given this situation, then in certain upper air conditions air flowing over a ridge or hill will be forced into vertical oscillation with a downwind configuration of the streamlines like that shown in Fig. 2. This is the phenomenon of lee waves.

It is known that the formation of lee waves can influence surface winds below the wave troughs⁵ and that material can be carried aloft and deposited downwind under the influence of the waves⁶. In a similar way lee waves could have transported virus particles from the Bryn farm area out over the Cheshire Plain. A trough over the source of virus, by enhancing up-currents, may have formed an unusually effective mechanism for carrying virus particles aloft. Once aloft, each "air parcel" is carried along the streamline pattern. Reports by glider pilots emphasize that flow in lee waves is often remarkably smooth⁷, so it seems possible that an air parcel will remain intact with a volumetric concentration of virus similar to the concentration at source. A particular air parcel might then be brought to ground level at the next trough and its virus content might be deposited or inhaled in the

Fig. 1. Outbreaks for days 1-10.

area immediately downwind of the trough where the winds become lighter. The remainder of the air parcel might then be carried up and on to the next trough. Such a hypothesis is especially attractive (it explains how virus from a single source could cause infections at a long range downwind), but if it is to be proven it must be shown that lee waves did occur on October 25 and/or October 26; that if they did occur they had a wavelength of approximately 18-20 km, the spacing of the clusters in Fig. 1; and that the crests and troughs occurred in the positions suggested by Fig. 2 so that pickup at source and downwind deposition could be explained.

Unfortunately, it seems that no meteorological observations were made in this area at the time, so the lee wave hypothesis cannot be directly proved or disproved. Theoretical grounds have therefore been used to estimate the occurrence and essential characteristics of these lee waves.

Table 1. CONDITIONS SUITABLE FOR LEE WAVES

Condition	Camborne upper air measurements							
	October: 24	October: 25	October: 26	October: 27	October: 24	October: 25	October: 26	October: 27
1. Marked stability at lower and/or middle altitudes — indicated by isothermal layer or temperature inversion	+	+	+	+	+	+	/	/
2. Wind speed increasing rapidly with height	-	-	+	+	+	/	-	+
3. Little variability in wind direction with height	-	-	+	+	+	+	-	-
4. High wind speed at hill crest greater than 20 knots	-	-	+	+	-	-	-	-
5. Frontal system in vicinity (Oswestry)	-	-	+	+	-	-	-	-

+, means condition satisfied; /, means condition marginally satisfied; -, means condition not satisfied.

Table 1 ranks the more important of the qualitative conditions associated with the formation of lee waves⁸ and indicates that October 25 and 26 were likely days for lee waves to form. Scorer⁹ has shown that, with the assumptions of frictionless, steady, laminar and isentropic flow over small ridges, waves are only possible when

Fig. 2. Profile through Bryn farm illustrating the lee wave hypothesis.

the variable l^2 reaches a marked maximum at lower or middle altitudes and then declines rapidly with height. l^2 can be estimated from upper air soundings of temperature and wind speed. Soundings at Camborne (West Cornwall) were used in order to make sure the sample was that of the undisturbed flow over Bryn farm. Plots of temperature, wind speed and l^2 for 2330 h GMT on October 25 are given in Fig. 3. They show the classic symptoms of conditions favourable for the development of lee waves: an isothermal layer, wind speed increasing with height and a pronounced maximum in l^2 at middle altitudes⁹. Similar plots for 1130 h GMT on October 25 were also obtained. SIGMETs from the Flight Information Centre at Preston also predicted the occurrence of lee waves from 1630 h GMT on October 25 to 0430 h GMT on October 26 (personal communication from S. A. Casswell).

The wavelengths of the lee wave formations were calculated from mean tropospheric wind speed using Corby's regression equation which was derived from radiosonde data⁸ and has been confirmed by subsequent investigators^{10,11}. The list of wavelengths in Table 2 shows that lee waves on the afternoon and evening of October 25 would have had the required wavelength of 18–20 km.

Table 2. CALCULATED WAVELENGTHS FOR OCTOBER 25–26

Oct. 25 0530 h	11.1 km
1130	17.5
1730	20.4
2330	19.4
Oct. 26 0530	16.7
1130	11.7
1730	13.6
2330	9.5

Finally, it must be shown that the positions of the crests and troughs of any existing pattern with a wavelength of

Fig. 3. Temperature, wind speed and l^2 for 2330 h on October 25, 1967, at Camborne.

about 20 km would conform to the positions shown in Fig. 2. The underlying topography can influence the amplitude and phase of the wave and so had to be taken into account in determining the position of the wave. Wallington's method¹² was used to calculate the streamline displacement, and the result is given by Fig. 2. Fig. 2 therefore represents atmospheric conditions as they probably were during the afternoon and evening of October 25.

Conditions at this time thus seem to have been conducive to the development of waves with a period of 18–20 km. The underlying topography would have ensured that the wave troughs in the air-stream formed over Bryn farm and over the downwind areas previously identified as "clusters". (The pattern of outbreaks in Fig. 2 was tested statistically with the method of Pearson¹³. The null hypothesis of randomness was rejected in favour of clustering at the 0.001 level.)

It seems that the lee wave hypothesis provides a plausible explanation of uptake of virus from a single (or localized) source, subsequent transmission at high concentration over long distances and deposition in relatively small areas downwind. Because neither primary outbreaks of foot and mouth disease nor lee waves are common events, the probability of a simultaneous occurrence of an initial outbreak at a site conducive to the development of lee waves and the occurrence of favourable conditions for lee waves seems quite low. It therefore seems that the probability of another similarly generated epizootic must also be quite low.

Book Reviews

NEW LIGHT ON A LEGEND

The Birth of Penicillin and the Disarming of Microbes
By Ronald Hare. Pp. 236+8 plates. (Allen and Unwin: London, July 1970.) 63s.

THIS is a clearly written, non-specialist, autobiographical account of the medical discoveries and scientific research which the author has been associated with or has contributed to. His research career started with six years in Sir Almroth Wright's department at St Mary's Hospital. Then, at the new Queen Charlotte's Hospital, he and Colebrook successfully attacked puerperal fever by epidemiological means and routed it when 'Prontosil' and the sulphonamides became available. There followed several years at the Connaught Laboratories, Toronto, with work on influenza virus, aspects of preventive medicine, and, finally, the emergency large scale production of penicillin during the war. Thereafter, until his retirement in 1964, he was professor of bacteriology in the University of London, at St Thomas's Hospital. The intrinsic interest of the matter is more than sustained by the modesty and humour with which the book is written.

The five chapters dealing with Hare's period (1925-31) at the Inoculation Department, St Mary's Hospital, Paddington, are historically the most interesting; Hare was in close contact with Fleming throughout, and is therefore able to give an authoritative account of the circumstances surrounding his discovery of penicillin there in 1928.

Chance is often said to have played a key part in Fleming's discovery, but its role seems to have been even greater than is usually supposed. Thus it seems that Fleming had already discarded the famous contaminated plate, and it was only the chance arrival of D. M. Price before the tray of plates was removed which led Fleming to re-examine some of them and to make what turned out to be perhaps the most important casual observation ever made. The plates had been sown with staphylococci, and, on one of them, Fleming noticed that around a contaminating fungus (*Penicillium notatum*) the bacterial colonies were undergoing lysis. While this phenomenon of bacterial antagonism crops up occasionally, this particular pattern—of staphylococcal colonies undergoing lysis in the vicinity of a growth of *P. notatum*—can only be produced under very special conditions; thus contamination by the fungal spore must occur at or not too long after the inoculation with staphylococci, and the plate must not be incubated, but held for some days at a rather low room temperature. Again, it may have been fortunate that the occupant of the room below Fleming's, C. J. La Touche, should have been working with fungi. After his discovery Fleming tested the eight penicillia in La Touche's collection and found that one produced penicillin and that this resembled his own contaminant. Hare's theory that the latter came from La Touche's room by way of the draughty stairway is more satisfying than the legend of a spore "coming in through the window from Praed Street"—especially as the window was probably never opened.

To some, the most absorbing parts of the book will be the description of the conditions of work in the Inoculation Department, its atmosphere of purpose, dedication

and diligence, and the sidelights thrown on the legendary characters of Wright, Colebrook, Fleming and others. Perhaps it is here that partial answers may be found to the riddle of why Fleming did not pursue penicillin. To be sure, there were material reasons too; penicillin was unstable, tedious to prepare and purify, staphylococci could become resistant to it, and opinion generally was against the belief that antibacterial agents might exist which could be given parenterally. But the reason proposed by Maurois in his biography of Fleming, namely active discouragement by Wright, is strongly discounted by Hare. Another reason, given by Fleming, is that he was not a chemist. He had working with him, however, two young colleagues, F. Ridley and S. Craddock—the former trained as a biochemist. Their careful work, carried out under difficult conditions, showed that penicillin became more stable at a faintly acid pH, that it could be concentrated by vacuum distillation, and that a protein-free alcoholic extract of the concentrate contained most of the penicillin. This work was dismissed in three lines in Fleming's original paper, and was apparently forgotten; yet had Fleming done some simple *in vivo* tests with such material he would almost certainly have got results as striking as those obtained at Oxford eleven years later. In fact, the first material injected intravenously into mice in 1940 had been prepared in precisely this way, and even the big doses given had had little observable toxicity.

Perhaps one's astonishment that Fleming abandoned penicillin is partly founded on a fallacy, namely the often repeated legend—which Fleming himself did not correct—that he knew all the time that penicillin would turn out to have remarkable curative properties. According to Hare, after an initial period of enthusiasm, Fleming's hopes faded; his inaction only becomes understandable in this context. Nevertheless, the intriguing but unanswerable question remains—would somebody else in Fleming's position have persevered?

N. G. HEATLEY

PROBLEMS OF PLENTY

Seeds of Change

The Green Revolution and Development in the 1970s.
By Lester R. Brown. Pp. xv+205. (Pall Mall: London, April 1970. Published for the Overseas Development Council.) 60s.

THIS very readable book is concerned with the course and the consequences of the agricultural revolution that was initiated with the introduction into many developing countries of short, fertilizer-responsive and photoperiod-insensitive, varieties of wheat and rice. These varieties were initially produced by Rockefeller and Ford Foundation workers, in collaboration with local scientists, in Mexico and the Philippines respectively. The short rices give higher yields than their tall predecessors without lodging, and the same is true of the short wheats, provided that irrigation water and nitrogenous fertilizers are also available. Because of their insensitivity to photoperiod they can be sown at any time of the year in low-latitude regions and will develop normally to rapid maturity, so that multiple cropping becomes possible.

Wide publicity has been given to the sudden and massive increases in grain production that followed the transfer of the new varieties to Pakistan, India and other countries. The high yields depend always on the supply of water, to such an extent that yield per unit of water begins to make more sense than yield per unit of area. More than ever the capacity of the land to support people must be measured by its water supply rather than by its area.

But the benefits of the new varieties were often accompanied by difficulties created by inadequacy of storage and transport facilities, and sometimes by the social unrest produced by exaggerations of inequalities of income.

Greater demands for inputs of manufactured goods and services resulting from agricultural prosperity have created jobs outside the farm sector. This is helping to cope with the unemployment and underemployment that are unrelenting products of population growth. The overall economic growth that is the consequence of agricultural growth will also provide some of the necessary jobs. Mr Brown suggests that all increased production, whether agricultural or industrial, should be labour-intensive in order to provide the maximum employment. Unfortunately, it seems to me that this Gandhian concept is unlikely to provide a reasonable income for the workers because of their diminished individual productivity. Moreover, to keep the land in continuous production with multiple cropping each year, harvesting, land preparation and sowing must take the shortest possible time—so the balance between men and machines favours the latter.

If there are no shortfalls due to disease, pests or weather, Mexico, Kenya, Iran, the Philippines, Pakistan, Afghanistan and Turkey will have surpluses of their staple grains following the 1970 harvest. India, Malaysia, Ceylon and Indonesia should join them by 1973 on current projections. The surpluses will buy perhaps 15 more years in which to attempt to solve the people-food equation, according to Brown. This leads him to suggest that restraints on population growth are more likely to be achieved with the improved prosperity that would occur if markets could be found for the grain surpluses. Such markets would most likely be in the developed countries whose present levels of agricultural production are often sustained by governmental intervention in the form of price support or tariff protection. Brown would like to see these policies discontinued. This argument will be hard to accept in the developed countries because the surpluses of the potential exporters are of uncertain extent and reliability, and population growth may well limit the period that the surpluses persist, while the quality of the new wheats and rices will restrict their acceptance on world markets. On this basis it would be unwise speedily to dismantle systems of agricultural policy and production that could be reconstructed only with great difficulty and considerable delay. At the same time, those who provide the secondary products and services for developing countries with grain surpluses will clearly wish to assist in the disposal of the surpluses on world markets and to consider the sources of their own imports.

Seeds of Change is a book of hope and of warning. It shows what the application of crop technology is doing to the developing world: telling of the initial relief and warning of the further actions that are necessary if we are not once more to regress into famine. It will be read with interest by agricultural research workers, by agriculturalists, economists and politicians.

RALPH RILEY

RECORDS OF POLLUTION

Environmental Pollution

Edited by Kenneth Mellanby. Vol. 1, No. 1. Quarterly. (Elsevier: Barking, Essex, July 1970.) 130s per annum.

Just a few years ago, the only journals with a declared interest in pollution were either medical or purely technical. There is now a flood of periodicals concerned with the state of our environment, some clearly propagandist or frankly cranky, while many of the more sober publications cover rather a wide range. Of these, *Biological Conservation* has, in the past, accepted a number of papers dealing with the ecological effects of pollution. *Environmental Pollution* was launched by the same publishers to specialize in such contributions from social, economic and engineering viewpoints as well as the biological, leaving its sister journal to deal with the management of

biological resources and the remedying of pollution damage. The high standard of the journal, were it in any doubt, is made plain by the list of its editors; Dr Kenneth Mellanby heads a board which includes Professor R. W. Edwards of Cardiff, Dr Gordon Goodman of Swansea and Dr J. E. Smith of Plymouth among its British members, together with ten eminent overseas scientists.

The first of four quarterly numbers contains four original papers and one review within 77 text pages, followed by two fairly lengthy book reviews. One paper is American and the remainder British; the journal will no doubt acquire a more international flavour as it becomes better known. Contributions will be accepted in French and German, when English summaries are required. Overseas readers may be annoyed to find that the English papers in this number, by contrast, do not include summaries in these languages. There are not only the standard "Instructions to Authors" inside the back cover but also "Notes for Authors" at the end of the text pages; the two are not entirely consistent. The more detailed "Notes" demand that all illustrations be submitted in duplicate, which seems not only a considerable burden in the case of an elaborate diagram but a quite unnecessary one. Perhaps a reduced copy is meant, such as most experienced authors submit for the use of editors or referees. The other instructions regarding illustrations are similarly confusing rather than helpful. I spend some time advising students on the preparation of their illustrations and should like to issue a general plea to journal publishers on their behalf to make these instructions not only clear but also reasonable.

The first paper is by a trio of workers at the editor's research station, Monks Wood, and deals with the presence and toxicity of polychlorinated biphenyl compounds in British wild birds—a very topical subject, in view of the partial responsibility assigned to PCBs for heavy bird mortalities in the Irish Sea last year. Jenny Baker's review of the effects of oils on plants is one result of her work at the Orielton Oil Pollution Research Unit and refers to eighty-nine sources, some of which are themselves shown as having large bibliographies; it is thus a very useful piece of background literature. F. B. Pyatt follows up the surveys of Fenton and later workers elsewhere with a study of the effects of air pollution on the distribution of lichens in the steelmaking town of Port Talbot. Further work from Monks Wood, the effect of DDT on tadpoles, is reported by A. S. Cooke and is followed by a paper from Professor Feder of Waltham, Massachusetts, on plant response to chronic ozone pollution.

A very subjective indication of the value of *Environmental Pollution* is that the review and two of the papers are of direct interest to me, while another of the papers may be indirectly useful. There is every sign that the value of this journal to workers in the field of pollution will increase, and it is to be hoped that its readers will include technologists as well as natural scientists.

A. NELSON-SMITH

HAZARDS FROM SMOKING

Inhalation Carcinogenesis

Edited by M. G. Hanna jun., P. Nettesheim and J. R. Gilbert. (Proceedings of a Biology Division, Oak Ridge National Laboratory Conference held in Gatlinburg, Tennessee, October 8–11, 1969.) (AEC Symposium Series, No. 18.) Pp. xii+524. (Clearinghouse for Federal Scientific and Technical Information, National Bureau of Standards, US Dept. of Commerce: Springfield, Virginia, 1970.) \$3.00.

Of all human organs, the lung offers the greatest surface area to the environment, and among British males the lungs are the most common sites of cancer. Inhalation carcinogenesis, the subject of this US Atomic Energy Commission symposium, is therefore of great importance

from the point of view of human health. Although most of the contributors are American the published papers give a reasonable account of the subject as it stood about a year ago. The hazards of inhalation carcinogenesis arise chiefly from occupational exposure, air pollution and smoking. It seems, however, to be more feasible to reduce the exposure from occupations and air pollution than that from smoking.

Until recently the association of exposure to inhaled toxic materials and the development of lung cancer was based solely on epidemiological and statistical findings. The papers given at the symposium are chiefly concerned with experimental carcinogenesis by gases, dusts and particulate clouds. The study of the biological effects of inhalation involves more sophisticated physical methods than are involved in the use of other routes of administration.

In the opening paper Professor Norton Nelson discusses the possible causes of lung cancer in man including radioactive materials, chromates, mustard gas, nickel, arsenic, asbestos and cigarette smoke. Miners' disease which Joachimsthal and Schneeberg identified as lung cancer in 1879 was one of the earliest recognized environmental cancers: lung cancer is still an occupational hazard among the uranium miners of Colorado. The first experimental lung cancers were induced with radioactive materials (^{144}Ce) by Lisco and Finkel and these and later experiments with radionucleotides are described by Dr W. J. Bair.

Some of the communications describe the techniques suitable for inhalation studies, the equipment for producing defined and controlled aerosols and mixtures of gases, particularly oxides of nitrogen. The design and construction of inhalation chambers and of cigarette smoking machines are described by several authors. Other papers describe experiments in which radioactive or chemically carcinogenic materials were implanted in different parts of the respiratory tract; although lung tumours have been induced by these techniques, they are not really caused by inhalation.

The effects of inhaled material include biochemical changes, such as denaturation of collagen fibres by ozone or nitrogen dioxide described by Buell, and an increase in DNA synthesis in the lungs of hamsters exposed to cigarette smoke found by Boren. Such exposure also causes lysis of lysosomes. The irritant gases, nitrogen dioxide and ozone, reduce resistance to infection by *Klebsiella pneumoniae* (Ehrlich, Henry and Fenters) or *Streptococcus C* (Coffin).

Laskin, Kuschner and Drew have induced carcinomas in rats by exposure to clouds of carcinogenic benzopyrene and irritant sulphur dioxide, but not by exposure to either carcinogen or irritant alone. Montesano, Saffiotti and Shubik induced bronchogenic carcinomas in hamsters by intratracheal instillation of benzopyrene and finely dispersed ferric oxide, but not with either chemical alone. These studies suggest that the combined action of irritant and carcinogen is necessary to induce lung tumours in animals. Auerbach, Hammond, Kirman and Garfinkel allowed dogs to smoke cigarettes through a tracheostomy tube. After the first attempts, the dogs seemed to enjoy smoking and smoked up to twelve cigarettes per day. Animals killed after 420 days had pulmonary fibrosis and emphysema and reports later than those under review have indicated that the procedure has induced bronchogenic cancer in some of the dogs. These are the first successful experiments to resemble the human experience with cigarettes.

The papers show that advances are being made in inhalation carcinogenesis and the experimental models for the genesis of lung cancer in man should make it possible to reduce the incidence of the disease by defining the environmental hazards and perhaps making it possible to manufacture less dangerous cigarettes.

E. BOYLAND

METABOLIC DISORDER

Early Diabetes

Edited by Rafael A. Camerini-Dávalos and Harold S. Cole. Associated Editor W. S. Gailmor. (Advances in Metabolic Disorders, Supplement 1.) Pp. xxi+486. (Academic: New York and London, March 1970.) 215s.

THIS book reports a group exchange of views of the First International Symposium on Early Diabetes. It is a monument to the fact stated in the first chapter of the book that "despite an enormous amount of work, there is still much confusion and disagreement concerning the primary lesion or lesions in diabetes mellitus". The galaxy of cross currents and statements, which are often contradictory in this investigation of diabetes, reflect the true state of the art. For those interested in becoming involved in these turbulent waters, the facets covered in the chapters dealing with genetics of diabetes in relation to animal and man, the function and control of the secretions of islet cells of the pancreas in normal and abnormal animals, and studies on insulin secretion in man would be valuable. The maternal-placental-foetal relationship in pregnancy and the association with carbohydrate intolerance is investigated, followed by definitions of pre-diabetes and latent or chemical diabetes. It is sad to relate that the natural history of diabetes occupies only 20 pages compared with 78 pages dealing with the treatment of early diabetes. This probably reflects the attitudes of those organizing the meeting rather than the real state.

This is not a book for the uninitiated or the tyro, but gives the new research worker an idea of the currents of interest and conclusions of past work. It is essentially a historical piece, full of the imperfections and changes that are inevitable in a subject which is rapidly changing. It gives little guide to the clinician engaged in the patient care field of better or improved approaches to treatment of this disorder. Fundamental to any research, however, is a knowledge of the approaches in the past that have not worked. This is an essential requirement for the research worker in metabolism and this book is recommended to them.

JOHN ANDERSON

POPULATION GENETICS

Evolution and the Genetics of Populations

Vol. 2: The Theory of Gene Frequencies. By Sewall Wright. Pp. vii+511. (University of Chicago: Chicago and London, April 1970.) 135s.

POPULATION genetics, like any other branch of science, is growing exponentially. It would be hoping for too much that all of the mathematical theory could be compressed into a book even of this size; for example, some of the important work of Kimura, Ewens, Malécot and others is referred to rather briefly. But, bearing this almost inescapable limitation in mind, it is truly astonishing how much is to be found here. The theory of gene frequencies began early this century with the observations of Yule, Castle, Hardy and Weinberg. If genes G, g have respective frequencies p, q , then in a large random mating population the genotypes GG, Gg, gg occur in the ratios $p^2 : 2pq : q^2$. This simple formula will in practice be modified by the occurrence of multiple alleles G_1, G_2, \dots, G_n , at one locus, by linkage of interaction between different loci, sex linkage, by mutation, selection, differential fertility, migration, inbreeding and assortative mating, cytoplasmic factors, and random fluctuation from generation to generation. Put together, these lead to an immense variety of possible situations.

Useful questions to ask are how a population will change under these combined influences, whether it will stay close to a "stable equilibrium" for long periods, how

far the composition of the population is liable to fluctuate under random change, and what are the correlations between relatives and the components of variance. These topics are dealt with in great detail, bringing the reader largely up to date in developments in the field and indicating where further information can be found. This is no small achievement in itself; what is more, a very considerable part of the contents is Sewell Wright's own work, spanning more than 50 years. He invented the methods of path coefficients, the inbreeding coefficient F , and the surface of adaptive values of mean fitnesses whose peaks indicate (nearly enough) stable states of the population. These techniques run through the book as unifying threads, though other methods of tackling the problems (such as the matrix theory of Fisher and Haldane) are also mentioned. The book gathers together information spread throughout an ever-increasing mass of literature, so that it will be a most useful reference book for all whose work concerns population genetics.

CEDRIC A. B. SMITH

BIOCHEMICAL GENETICS

The Principles of Human Biochemical Genetics

By Harry Harris. Pp. ix + 328. (North-Holland: London and Amsterdam, 1970.) 117s (\$14.00) boards; 53s (\$6.30) paper.

Books by Professor Harry Harris have a creative aspect altogether their own. In 1953 he published *An Introduction to Human Biochemical Genetics* and this was almost certainly the first time the term human biochemical genetics was used. It was a milestone in the development of that subject; nothing like it had appeared since Garrod's last book in 1923. In 1959 followed Harris's textbook *Human Biochemical Genetics* which firmly established the new discipline. At that time it was possible to cover the field completely, but, in 1970, one book can no longer do this and the new work has become *The Principles of Human Biochemical Genetics*. Nevertheless, these principles are illustrated by examples, many of which are taken from human haemoglobins and certain enzymes such as glucose-6-phosphate dehydrogenase and serum cholinesterase, and at one place or another almost all aspects of human biochemical genetics are referred to. For example, there is a table listing thirty enzyme and protein polymorphisms, supported in each case by the methods of detection and references. Another table lists twenty-five disorders caused by specific enzyme deficiencies (inborn errors of metabolism); any enzyme deficiency which has not been discussed elsewhere is briefly annotated and again references are given.

There are chapters on gene mutations and single amino-acid substitutions, the "one gene one polypeptide chain" theory and its implication, on duplications and deletions and their effects on protein structure, on gene mutations affecting the rates of protein synthesis, and on the quantitative and qualitative variations of enzymes. Other sections of the book are more specific and deal with inborn errors of metabolism, the enzyme and protein diversity in human populations, the blood group substances, the molecular pathology of inherited disease, the effects of dominance and recessivity, heredity and environment. The illustrations are ingeniously simple, and together with the tables, often throw an entirely new light on a problem. This applies, for example, to the felicitous way Harris lists the haemoglobin variants, how he illustrates the production of hybrid proteins, and how intragenic crossing-over may give rise to haemoglobin Lepore in the case of haemoglobin, or to the appearance of a triplicated allele in haptoglobins.

Harris states in his preface that this book has grown out of a course of lectures given at the Galton Laboratory,

intended not only for those specifically studying human genetics but also for biochemists, biologists and medical men. It is exactly that circle of readers which will find not only information but also inspiration in this book.

It is worth mentioning that the book is excellently produced and the paperback is good value at 53s.

H. LEHMANN

VISUAL PERCEPTION

Perception Through Experience

By M. D. Vernon. (Methuen's Manuals of Modern Psychology.) Pp. x + 306. (Methuen: London, May 1970.) 55s.

THE title of Professor Vernon's third book on visual perception catches the attention. When we read in the introduction that "knowledge and experience are particularly involved in the inferences we commonly make as to the nature of objects and events", we look forward to reading about how experience does enable us to make these inferences about perceived objects. This sort of issue is now widely recognized as being central to the problem of perception. How is it that from the fragmentary and disjointed data arising from fleeting two-dimensional patterns on the retina, we have the overwhelming impression of a stable world filled with people and things? Clearly, systems of perception interpret sense data as objects. Equally clearly this process requires a contribution from within, of stored knowledge about the nature of the world, which must be many times greater than the contribution made by sense data at any one moment. It is the interpretation of the sense data in terms of our knowledge which we see, not the sense data themselves.

Professor Vernon does not set out to explain how these processes occur. Instead she reviews a fairly wide range of experimental literature, doing "little more than allude to the various theories which have been advanced". She does cover a lot of experiments, however, ranging from the recent work of Fantz and Bower on the visual abilities of very young children, through attentional processes and some of the standard perceptual topics such as the constancies and seeing movement, to the relation of motivational and personality characteristics to perception. Rather surprisingly, in view of the title, there is not a great deal about perceptual learning, although there is quite a lot of material on children.

The book is said to be intended for students taking degree courses in psychology. Though it contains descriptions of many interesting experiments, I rather doubt whether undergraduates have the experience to perceive the interest or importance in experimental studies until the data are embedded in reasonably well articulated explanations and theories. The author takes a different view, arguing that extensive knowledge, which she here attempts to provide, should precede theoretical argument.

KEITH OATLEY

FAT SOLUBLE VITAMINS

Fat Soluble Vitamins

Edited by R. A. Morton. (International Encyclopaedia of Food and Nutrition, Vol. 9.) Pp. xii + 530. (Pergamon: London, Oxford and New York, April 1970.) 120s; \$16.

THIS is the second to appear of the twenty volumes of the "International Encyclopaedia of Food and Nutrition" now in preparation. Volumes are being issued as they are completed and without reference to their position in the series.

Professor R. A. Morton has assembled a distinguished team of authors to review all aspects of the chemistry and biochemistry of the fat soluble vitamins and their significance, role and use in human and animal nutrition. After an introductory chapter setting the field in perspective, chapters are devoted to the chemical structure and physical properties of the vitamins, their biosynthesis and their bioassay. The biochemistry of vitamins A, D and K is discussed in separate articles and there is a comprehensive chapter on the tocopherols. The mode of action of the fat soluble vitamins is still largely unknown, but the well established role of vitamin A in vision is discussed in some detail. By way of digression an article is given to lipoic acid which, although not generally classed as a vitamin because it is not required by higher animals, is a growth factor for some microorganisms and has a clearly defined biochemical role. The remaining chapters are concerned with the more technological aspects of the synthesis and utilization of the fat soluble vitamins and with their application in practical nutrition.

This volume is a useful and self-contained book. The individual chapters are well written and, although differing somewhat in their breadth and depth of treatment, they all include adequate references to sources of further information. Unfortunately it is evident that most of the articles were completed during 1967. While it is recognized that a book of this sort can never be absolutely up to date, it is clear that the long term value of the encyclopaedia will largely depend on the ability of the editors to carry out their intention to provide continuous up-dating by producing an annual review to report recent advances in the fields covered.

J. W. G. PORTER

PHILOSOPHY AND ATOMIC PHYSICS

Atomic Order

An Introduction to the Philosophy of Microphysics. By Enrico Cantore. Pp. xi+334. (MIT: Cambridge, Massachusetts, and London, April 1970.) 117s.

THE aim of the book is to contribute towards a better understanding between the humanist and scientific cultures, and the specific problem discussed is the lack of communication between philosophers and scientists. The method adopted is called inductive-genetic; that is, the investigation is limited to a well established scientific discipline, namely atomic physics, and the intention is not only to examine the consistency and completeness of quantum theory, but also to show how the gradual gathering of experimental evidence has necessitated the formation of the theory. The investigation is meant to serve as the basis for discussing the interdependence of science and philosophy.

In the first half of the book, the author gives a survey of atomic physics, and, first of all, he succeeds in explaining how quantum theory is able to account for all the evidence about atoms and atomic aggregates. Calculations are omitted, but essential experimental results are amply presented in tables and diagrams, and there are plenty of references for further readings. As to the philosophical analysis, it is essentially ontological. According to the author, to observe an atomic object it is necessary to disturb it; that is, the object must interact with the instruments of observation, and, because of the existence of the fundamental quantum of action, we have uncertainty relations. But what is then the atomic object, the undisturbed state of which it is fundamentally impossible to observe? To the author it seems to be an essentially classical particle, for, when talking about the wave function representing the atomic object in quantum theory, he states that the microentity certainly does not fill up the entire volume occupied by the wave, but remains a concentrated piece of matter all the time (p. 241). In fact, this idea is further developed using the concept of local motion,

which is considered to be just as real at the atomic level as in classical mechanics. But the author totally fails to convince the reader that this conception of the atomic object is concordant with the experimental basis of wave mechanics; that is, with the basis of quantum theory itself.

The principle of complementarity is very sketchily discussed, but it is said to be very important to the philosophical considerations. It seems, however, as if the author has not grasped the principle fully, because he persists in speaking of disturbance of atomic objects by observation. According to Bohr, this way of talking should be avoided because it implies the existence of a world of undisturbed physical objects, which is fundamentally non-observable. An analysis of Bohr's phenomenon-centred terminology would have been appropriate, at least as an alternative to the ontological point of view.

Thus I find the philosophical part of the book rather confusing and also tedious. The same ontological viewpoints are repeated under different headings, but without clarification of the central epistemological problems.

T. BERGSTEIN

ACCELERATOR PHYSICS

Intermediate Energy Nuclear Physics

By W. O. Lock and D. F. Measday. Pp. xiii+320. (Methuen: London, April 1970.) 85s.

THIS book is a revised and expanded edition of *High Energy Nuclear Physics* by W. O. Lock. It deals chiefly with the nuclear and elementary particle physics which can be explored with accelerators in the energy range 100–1,000 MeV. The change in title does not reflect a change in content so much as the change in accelerator technology which has occurred during the past 10 years. The book is intended as an introductory text for postgraduate students.

The first four chapters contain a mixture of basic nuclear and elementary particle theory, a section on accelerators and experimental techniques and one on the properties of the electrons, muons, neutrinos, pions, nucleons and some other light mesons and baryons. In the next four chapters the experimental evidence is given on the interactions of pions, photons, electrons and nucleons with nucleons. The last three chapters describe the interactions of photons, electrons, muons, pions and nucleons with nuclei.

This is an extremely wide field to cover in a single book and there is not enough space to give more than a superficial treatment of many of the topics. It therefore seems a pity that some space has been used to reproduce basic theory which can be found in most books on quantum mechanics. The most useful chapters will probably be those on the interactions between elementary particles and nucleons, and here the text is supplemented by many graphs of experimental results. The experiments are discussed in the light of predictions of modern conservation laws and symmetries. A useful feature is the bibliography and the long list of references given for each chapter.

It would have been more satisfactory if certain sections of this book had either been expanded considerably or left out, but many people will find it useful as a rather broad review of the subject.

R. C. BARRETT

FORMULAE FOR ASTROPHYSICISTS

Elementary Processes for Cosmic Ray Astrophysics

By V. L. Ginzburg. (Topics in Astrophysics and Space Physics, No. 1.) Pp. viii+131. (Gordon and Breach: New York and London, April 1970.) 105s (\$12.60) boards; 70s (\$8.40) paper.

THIS book is based on the lecture course which the author prepared for the 1966 Summer School in Les Houches, but which was never actually presented, with the addition

of a separate section giving a comprehensive and more up to date treatment of synchrotron emission and reabsorption. The rest of the book covers radiative processes—the Compton effect, thermal bremsstrahlung radiation, ionization losses and collective plasma processes—thoroughly, but in rather less detail. Particle production receives only a very brief treatment, and the discussion of the generation and absorption of γ and X-rays receives less prominence than one might expect from the title of the volume.

On the whole, this is a useful book which gathers together many of the formulae required by those working in the fields of high energy astrophysics. But once again the relatively high cost of what is a rather slim volume requires comment. The price is not excessive by the standards of Gordon and Breach, but it is difficult to see why these standards should differ so much from those of other publishers, particularly when the physical construction of the book and the incidence of minor misprints suggest that no correspondingly high standards were maintained in its manufacture.

JOHN GRIBBIN

GEOMORPHOLOGY OF THE SAHARA

L'Évolution Continentale Post-Hercynienne du Sahara Algérien

(Saoura, Erg Chech Tanezrouft, Ahnet-Mouydir.) By Georges Conrad. (Centre de Recherches sur les Zones Arides: Série Géologie, No. 10.) Pp. 527+11 plates. (Editions du Centre National de la Recherche Scientifique: Paris, 1969.) 120.40 francs.

THIS well organized and handsomely illustrated *thèse* deals with the geomorphological evolution of a large segment of the north-western Sahara, between the Atlas of Western Algeria and the north-western slopes of the Hoggar.

After dealing with the geological antecedents (Palaeozoic to early Tertiary), the core of the study considers successively the late Tertiary, the Plio-Pleistocene, the early, middle and late Pleistocene, and the Holocene. A series of excellent sections is here used to describe patterns of sedimentation or erosion, with a series of informative palaeogeographic reconstructions. During this period of time, climate fluctuated within a range of hyperarid, arid, subarid and semiarid, with an overall trend to greater aridity and less accentuated oscillations. Different sedimentary and pedogenetic processes are repeatedly identified for the northern and southern parts of the study area, presumably reflecting latitudinal contrasts of climatic change. So, for example, during the course of the Pleistocene, ferricretion among the Hoggar foothills repeatedly corresponded to calcerection in the Saharan lowlands and on the Atlas slopes, while two phases of silicification during the later Tertiary were restricted to the southern half of the region. Part two serves as an appendix to describe particular sediments and soils: torba (fine Tertiary basin fills consisting of attapulgitic, carbonates and detrital quartz); evaporites; lacustrine dolomites; calcareous and ferruginous crusts; silcretes; daia (sink-hole depressions) fills; eolian sands; fech-fech (powdery, fine but heterogeneous surface deposits rich in soluble salts and lime dust); and clay minerals. The final section provides a general synthesis, with comparative stratigraphy from other parts of the western Sahara, the Chad Basin and the Senegal Delta (including a detailed chart and list of ^{14}C dates).

This volume is very welcome, providing a unique documentation of the late Cainozoic of the north-western Sahara. Even if matters of stratigraphy or interpretation require revision in the future, the wealth of objectively presented data will remain valuable to all interested in the Saharan world.

KARL W. BUTZER

Short Notices

Women in the Field: Anthropological Experiences. Edited by Peggy Golde. Pp. 343. (Aldine: Chicago, July 1970.) \$8.95.

THIS fascinating anthology of experiences, opinions and theories by thirteen eminent lady anthropologists was conceived as a guide for students who are pondering how and where they should pursue their studies of man and his ways. Each contribution is a personal account of one woman's experiences as an outsider breaking into a strange culture. The restriction to one sex is no empty gimmick—women face special problems in alien societies, and, in any case, it is worth considering their place in a profession that seems to have done well for a relatively large proportion of them. Clearly it is a profession in which rewards are hard won; there are hair raising dangers and depths of despair in plenty in this book. Ruth Landes was accused of being both a prostitute and a communist spy in Brazil, and Peggy Golde retreated to the church as the only place in a Mexican village where she could have a cry. Margaret Mead, however, reports no such hostility in New Guinea. As an insight into the motivation and way of life of the woman anthropologist in action, this book is excellent, far better than its sober cover and rustic title suggest.

Gilbert White's Journals. Edited by W. Johnson. Pp. xlviii+463. (David and Charles Reprints: Newton Abbot, May 1970. First published in 1931.) 105s.

WITH the modern fashion for centenary celebrations and the like of one sort and another, the publishers of reprints have an assured market and it can be no coincidence that a reprint of Walter Johnson's selection from Gilbert White's *Naturalist's Journal* is published this year, the 250th anniversary of White's birth. For devotees of the *Natural History and Antiquities of Selborne*, who missed Johnson's 1930 edition and who cannot manage a visit to the British Museum to see the original manuscripts, here then is a chance to buy a partner for White's classic. They will not be disappointed—the *Journal* was used by White as a sourcebook for his *Natural History*, and it abounds with similar delightful and acute observations of life around him. While commenting daily about the birds and the bees, Timothy the tortoise, his neighbours and other goings-on in the nearby gardens and fields, White also slips in the unexpected, as on May 4, 1778, when he complains about the five running firings on the day the King and Queen visited the fleet at Spithead, which "shook my house and made the windows jar": Noise Abatement Society take note.

Permafrost in Canada: Its Influence on Northern Development. By R. J. E. Brown. (Canadian Building Series, 4.) Pp. viii+234. (University of Toronto: Toronto; Oxford University: London, July 1970.) 120s.

IT is a chilly thought that half of Canada's land surface lies in the region of permafrost or perennially frozen ground—ground which for several continuous years remains below freezing point. The layer may vary in thickness from only a few inches to more than 1,000 feet in the extremes, the thickest recording in Canada being 1,500 feet at Winter Harbour on Melville Island in North West Territory. Until recently, such inhospitable land hampered all but the slightest development, but, as is shown in this book, it is now technically possible to build almost any engineering structure in the Canadian permafrost—roads, railways, bridges, buildings, and the like—even in the worst regions, though its construction cost is considerably greater there than in more temperate climes. In a comprehensive survey of the nature of permafrost and of its effect on the development of Canada's frozen north, Dr Brown shows that, in his search for greater wealth, man's activities have no bounds.

Correspondence

Geophysical Theory

SIR,—May I, while thanking Professor Runcorn for the greater part of his review of the new edition of *The Earth* (*Nature*, 227, 525; 1970), reply to his critical remarks concerning certain parts of it?

He refers to my "robust prejudices" and states that I indulge in "selection (selective?) quotation". I admit to a prejudice, namely that in an alleged explanation the conclusions should follow from the hypotheses, and that if the hypotheses lead to conclusions different from the facts there is something wrong with them. This prejudice is shared by most scientists.

As for selection, I admit that I have not read everything published in support of continental drift. I think that I have given reasons why the alleged explanation does not explain things that have happened and explains too many things that have not happened. On the other hand, I have not seen any work by a supporter of drift that even mentions that there are difficulties.

From Runcorn's review it would be inferred that I have not treated imperfection of elasticity apart from fracture. Following on the work described in the book (p. 331 *et seq.*) Crampin and I^{1,2} have recently published further work, and the form that we find forbids convection and continental drift. It gives quantitative explanations of facts far beyond the original data. Most seismologists concerned with damping use a law that departs even more than ours from one type that permits convection.

Since the final proofs were passed, there have been extensive and severe criticisms of continental drift from the geological point of view by Meyerhoff³ and Biswas⁴.

Yours faithfully,

HAROLD JEFFREYS

St John's College,
Cambridge.

Wayward Bacterium

SIR,—Permit me to call to your attention evidence of a misconception on the part of your writer responsible for the article "Lunar Bacteriology—Bacillus by Rocket" (*Nature*, 226, 1000; 1970). The question is asked, "But how did the bacterium escape through the tight sterility net applied to all extraterrestrial space missions?"

Early in the decade of the 1960s there was concern for terrestrial contamination of the Moon; but as the matter was studied, it became apparent that, though terrestrial life might survive on the Moon, it could not multiply in that adverse environment, and it could therefore be no threat to lunar life if it existed. Subsequently the only biological constraint on lunar missions has been the expressed opinion of the International Committee on Space Research (COSPAR) that careful sterilization is desirable for drills designed for deep lunar subsurface boring. NASA has gone one step further, however, and on the basis of a recommendation by the Space Science Board of the National Academy of Sciences has kept its lunar landing hardware as biologically clean as was practi-

cal. This action resulted in approximately 5×10^6 viable spores being aboard Surveyor 3 at the time of launch, as compared with 1×10^8 to 1×10^9 spores for a spacecraft assembled without cleanliness controls.

In contrast is the constraint placed on planetary missions. COSPAR has recommended that launching states assure that there shall be only one chance in one thousand of contaminating a planet deemed important for the investigation of extraterrestrial life during the period of biological exploration. NASA has closely adhered to this requirement by biasing the trajectory of non-sterile flyby missions away from the planets sufficiently so that the probability of direct impact is very small, and no ejecta can reach the atmosphere. When missions are launched to land capsules on Mars, those parts of the missions intended to land on the planet's surface will be sterilized to the extent that they will have a probability of less than 1×10^{-3} of contaminating the planet.

The United States is very aware of and is actively engaged in meeting its responsibility to protect the planets from biological contamination carried on its spacecraft. Its responsibilities with regard to the Moon have been more than met.

Yours faithfully,

LAWRENCE B. HALL

French Nuclear Tests

SIR,—The welfare of South Pacific communities is increasingly at risk in the face of relentless testing of nuclear weapons in French Polynesia. Public outcry in Europe prevented France from continuing her test programme in Algeria. However, the protesting voices of small South Pacific governments have been ignored.

We are faced with increasing evidence of the hazards of uncontrolled radioactivity. While the extrapolations of Sternglass¹ may overstate the threat, we cannot be complacent. Similar, more moderate, warnings by Gofman and Tamplin² and others on the dangers of the infamous "permissible" level of radiation are generally accepted in the scientific community.

While the lasting danger to the people of the South Pacific lies in a general atmospheric contamination which will be shared, to an extent, with the rest of the world, a more immediate threat exists from contaminated fish. Certain of the large migratory fish such as tuna might feed on smaller fish dependent on heavily contaminated plankton drifting from the test area. Such deadly migratory fish could turn up in catches all over the Pacific.

Coral reef organisms have a great capacity for concentrating radionuclides. Data of Odum and Odum³ show a thousand-fold concentration in coral. Molluscs also are notoriously efficient concentrators of radionuclides and these organisms constitute a major part of the diet of South Pacific Islanders.

The French Defence Minister, M Debré, while in Tahiti recently, had the audacity to say that atomic scientists had "proved that the nuclear tests left no radioactive contamination in the area". British, New Zealand and

Australian government reports⁴⁻⁶ give extensive data to the contrary and R. S. Cambray (personal communication), senior author of the British report, points out that about 75 per cent of the long-lived activity in the southern hemisphere in 1969 was due to the 1968 nuclear tests. This percentage is presently rising as the 1970 series nears completion.

Can the scientific community remain complacent in the knowledge that the French government intends to continue testing in the South Pacific next year, and under conditions of reduced safety? M. Debré has underlined his government's lack of respect for the people of the area by recently announcing a reduction of what he terms "the surfeit of useless precautions".

I call on responsible scientists to use their influence, through the various scientific organizations, to enlighten their governments on the radiation hazards to which South Pacific communities are exposed and to impress on these governments the need to pressure France, as a humanitarian gesture, to cease nuclear testing in the South Pacific.

Yours faithfully,

GRAHAM B. K. BAINES

Journal Dissemination

SIR,—One major impediment to the further development of science and advanced technology in developing and underdeveloped nations is that scientific journals reach us much more slowly than they reach laboratories in the developed nations. There are two reasons for this: our library budgets are small, so that to maintain a maximum coverage we are limited to seamail subscriptions. Second, in many cases the postal services are so bad that even after the journals reach the country they may be delayed several months before reaching the laboratory.

It has been suggested that the IATA might accept the shipment of scientific journals at reduced rates, but this piece of special pleading would, we suppose, be resisted since many other people may also feel that they merit special consideration.

We make the following proposal: that every scientific journal should be published in two forms simultaneously, in the present form and in microfiche (or microfilm). Any subscription to the journal would automatically consist in a subscription to one copy in each form. The microfiches could easily be sent by airmail letter post (this would be much faster even than present airmail subscriptions because letters receive very much higher

priority than parcels or printed matter even when the latter are sent airmail) at a very low cost and if the conventionally bound journal took several months to arrive by sea it would not matter so much. The additional cost of making the microfiches centrally and in such numbers would be very small and the problem of copyright would not be more acute than at present since the microfiches would be sent only to people who receive the journal by subscription in the normal way.

We are aware that certain journals are already offered in both forms but with the subscriber having to make the choice between them. We believe that our proposal is superior and that the additional cost would be sufficiently small that the price of subscriptions need not be raised significantly.

Finally, we feel that the proposal would also benefit science libraries with more favourable postal services since they would need to keep the bound journals only for a year or two while keeping a complete record of the literature on microfiche.

Citation Indexing for Studying Science

SIR,—E. Garfield's list (*Nature*, **227**, 669; 1970) of authors most cited in 1967 features a selection of authors of techniques for cytology, which prompts comment on the objectivity he claims for citation indexing, in the light of current writing and editing practice in this field leading to arbitrary omissions.

A citation index will, for example, disregard the large number of times the term Feulgen is used, without bibliography and yet with precise meaning. Lead citrate staining is mostly mentioned with a citation; uranyl acetate, used for the same purpose and perhaps reported in the same sentence, without one. Citation practice for embedding media is varied and not always apt. Fixation with glutaraldehyde ranked frequent citation for a time; that with osmium tetroxide rarely does unless particular buffers are added. Because these techniques rarely form "key words", there is no automatic check on this selectivity.

This does not deny that the authors frequently cited are important and welcome influences in several fields. An appreciation of the state of their fields, however, and of their influence on them, will escape index researchers content with the objectivity gained by not reading the literature.

Yours faithfully,

P. T. P. OLIVER

Institute of Genetics,
University of Glasgow,
Church Street, Glasgow W1.

Announcements

University News

Professor Jack Diamond, Beyer professor of mechanical engineering, will succeed **Professor S. G. F. Brandon** as a pro-vice-chancellor of the **University of Manchester** in October. **Professor R. A. C. Oliver** is retiring from the Sarah Fielden chair of education and will be succeeded by **Professor Frank Musgrove**, University of Bradford.

Mr John B. Wilkinson, head of the Unilever Research Laboratory, Isleworth, has been appointed visiting professor in the Department of Chemistry, **University of Surrey**.

Professor Peter V. Hobbs has been appointed professor of atmospheric sciences in the **University of Washington**, Seattle.

Appointments

Lord Nelson of Stafford, chairman of the General Electric and English Electric companies, has been elected president of the **Institution of Electrical Engineers** for 1970-71.

Mr F. W. Dunning has been appointed curator of the **Museum of Practical Geology**, South Kensington, in succession to **Mr A. J. Butler**, who is retiring from the office in order to undertake a special assignment in the Institute of Geological Sciences.

Dr Stevenson Buchan will retire as deputy director of the **Institute of Geological Sciences**, South Kensington, in April 1971. He will be succeeded by **Dr A. W. Woodland**, assistant director, Northern Region England and Wales, and head of the Leeds office of the Institute.

Miscellaneous

Professor R. R. Haering of Simon Fraser University has been awarded the **Herzberg medal** of the Canadian Association of Physicists.

Mr S. W. K. Morgan, **Dr S. E. Woods**, **Mr J. Lumsden**, **Mr B. G. Perry** and the late **Mr L. J. Derham**, of the Imperial Smelting Corporation Ltd, Avonmouth, have won the **Royal Society Mullard award** for 1970 for their outstanding contributions to the concept and development of the zinc blast furnace. The award, which consists of a gold medal and a prize of £1,000, is made annually for an advance in science, engineering or technology which has in the past ten years led directly to national prosperity in the United Kingdom.

- * The Council of **The Royal Society** has awarded the following fellowships, tenable for two years from October 1: **Mr and Mrs John Jaffe donation research fellowship**, to **Dr A. E. Hill** to study the molecular assembly of an ion pump at the Hebrew University, Jerusalem, and the University of Cambridge; **Pickering research fellowship**, to **Dr R. K. Thomas** to continue his work on infrared and photoelectron spectroscopy at the University of Oxford; **Stothert research fellowships**, to **Mr P. R. Cook** to work on genetic activity in fused cells at the University of Oxford, and to **Dr G. D. Lindsay** to undertake chemical modification studies on insulin at the University of Sussex. The Sorby Research Fund Committee has awarded the **Sorby research fellowship** to **Dr Bridget I. Baker** to study the functions and control of teleost pituitary secretions at the University of Sheffield.

ERRATUM. In the review, "Skyie-Influences", by N. W. Pirie (*Nature*, **227**, 525; 1970), the word "courses" in line 20 of the first paragraph should read "sources", and the word "prebiotic" in line 14 of the second paragraph should read "probiotic".

International Meetings

September 2-4, **Man-Computer Interaction**, Teddington (Dr Christopher Evans, Conference Organizing Committee, Division of Computer Science, National Physical Laboratory, Teddington, Middlesex).

September 11, **Land Management in the Seventies: Concepts and Models**, Seattle (Land Management Conference, Battelle Seattle Research Center, 4000 NE 41st Street, Seattle, Washington 98105, USA).

September 16-October 24, **Plastics at the Design Centre**, London (The Information Officer, British Plastics Federation, 47 Piccadilly, London, W1V 0DN).

September 20-25, **International Federation of Societies of Cosmetic Chemists Conference**, Barcelona (The General Secretary, International Federation of Societies of Cosmetic Chemists, 56 Kingsway, London WC2).

September 22-24, **Critical Factors in the Application of Diesel Engines**, Southampton (Mrs M. Wyatt, Institution of Mechanical Engineers, 1 Birdcage Walk, Westminster, London SW1).

September 28, **The Theory, Design and Applications of the Optics Technology Inc. Modulation Transfer Function Analyser**, London (Techmation Limited, 58 Edgware Way, Edgware, Middlesex HA8 8JP).

HOW TO BUY NATURE

Volumes start in January, April, July and October, but subscriptions may begin with any issue.

The direct postal price per subscription for one copy of NATURE each week is:

12 MONTHS (52 issues and 4 indexes)

Great Britain and Eire.....£14 0 0 each
United States of America.....(by air freight).....\$48 each
Canada.....(by air freight).....\$52 each
Elsewhere overseas by surface mail.....£14 0 0 each

(Charge for delivery by air mail on application)

*Shorter periods *pro rata*. (Minimum three months.)

Is Supersonic Transport worth the Noise?

THERE is now a serious danger that intemperate expressions of opinion about the desirability or otherwise of supersonic commercial aircraft will seriously complicate the process of deciding what use to make of these machines. Senator William Proxmire's outburst in Washington last week (see page 884) is, for example, a splendid illustration of how over-ardent advocacy can destroy its own objectives. Unhappily for all concerned, there is bound to be the greatest difficulty in striking an accurate balance between the advantages and the disadvantages of technical projects as novel and as expensive as the two enterprises now well under way on both sides of the Atlantic. The United States Government, at the urging of Congress, has soberly acknowledged the importance but also the difficulty of the task by setting up an organization to which both NASA and the Federal Aviation Agency will contribute manpower and ideas so as to make a better cost-benefit analysis of the SST project than any that exists so far, and it would have been a great help if Senator Proxmire could have toned down the language in his report at least until the first findings of the working group are available, most probably in a preliminary form in September and more completely by the end of the year. Certainly he would have done a greater public service if he had been able to carry the dispute about the SST outside the narrow field within which it has so far been artificially and unhelpfully confined.

Arguments about the likely cost of the Concorde and the SST which tend to show that both projects are unlikely to make a profit for the governments concerned and may even cause permanent economic damage to the aircraft manufacturers as well as by now so familiar as to be arid. For whatever may be said about the balance of cost and commercial benefit, the sums of money which are involved are small by the standards on which most governments operate. In the United States, for example, the total cost of the SST programme is merely four or five per cent of the cost of the Apollo programme. And even the French and British governments between them will not be seriously embarrassed by the money that is actually spent on building and operating the two prototypes of the Concorde, now at the threshold of the trials intended to show whether the design performs sufficiently well to allow the aircraft to fly the Atlantic without having to leave its passengers behind.

The way in which skilled people have been employed on the two projects when there are other tasks that might have been attempted is a more serious objection to present plans, but so long as all three governments are for practical purposes committed to continuing support for their domestic aircraft industries, the people concerned may just as well be used for building super-

sonic transports as for other kinds of flying machines. In other words, even if Mr Proxmire is right in saying that governments will find that their investment is not recoverable, this will be neither a great surprise nor an overwhelming tragedy.

But will the supersonic aircraft ever be commercially viable? This is a more difficult question to decide. Confident predictions one way or the other are at this stage mistaken, for the true test of the commercial viability of these projects is not whether the manufacturers can sell enough copies to pay off their tooling costs but whether the airlines which buy the machines can then operate them commercially without further rigging the fare structure in such a way as to impose unjustifiable levies on air travellers. The chances are that both the supersonic aircraft being developed in the West will somehow surmount the first of these hurdles. If the Concorde is a technical success, there is every likelihood that the British and French governments will find themselves supporting the purchase by their nationalized carriers of enough copies of the Concorde for other competing airlines to be forced to follow suit. Then, by the late seventies when the Boeing aircraft comes into service, the commercial advantages of that larger and faster machine will probably ensure that most of the airlines then equipped with the Concorde will switch to the SST. The result will be that airlines will find themselves having to invest in new equipment at a rate exceeding \$500 million a year for a decade or more to come. The outcome could be an increase in the cost of air transport and not the decrease that progress should bring. The spate of re-equipment in the past few years has already been a powerful impediment to the continuing reduction of fares. The grim possibility that the coming of the supersonic transports might drive up fares is the point to which attention should be directed.

It goes without saying that a proper concern for the nuisances that supersonic aircraft will cause should be counted fully among the boundary conditions with which commercial supersonic aircraft must conform. There is no reason why people living near airports or beneath the flight paths of supersonic aircraft should be incommoded by their arrival on the scene. Indeed, most airports are too noisy as things are, and need to be made much quieter. The coming of the supersonic aircraft should be an opportunity for improving conditions, not an excuse for letting them become worse. If it follows from this that the flight of supersonic aircraft must be restricted to routes between terminals where noise is comparatively unimportant, that is merely a restriction that airlines should be compelled to take into their calculations. In the long run, it may even be necessary to weigh the chance that

investment in the development of better aircraft engines against the cost of building entirely new airports in places where they cannot be a nuisance. This, after all, is merely what the systems analysts would say.

Noise apart, the other environmental hazards now commonly associated with the prospect of commercial supersonic aircraft are for the time being hypothetical, which is not, of course, to suggest that they can be ignored. Unhappily, however, there is now among the environmentalists a tendency to suppose that a hypothetical danger is potentially a disaster until it can be shown to be entirely negligible. One result has been a needless exaggeration of the danger that supersonic flight will so load the lower stratosphere with unaccustomed quantities of water vapour and hydrocarbon soot that the thermal balance within the atmosphere will be upset. This is a matter to which the President's *ad hoc* working group on the SST drew attention more than a year ago, and obviously it cannot lightly be dismissed. Fortunately, however, this is not an issue which can be settled only by launching fleets of supersonic aircraft into the stratosphere and waiting to see whether there is a deterioration in the climate on the surface of the Earth. As good luck will have it, the past few months have seen valuable steps towards the better understanding of the thermal balance in the atmosphere, chiefly by the use of improved instruments in Earth satellites. With wit and moderate deliberation, it should be possible to improve enormously on the present understanding of what water vapour in the stratosphere is likely to accomplish. The chances are that here as in many other questions of the influence of human activities on the atmosphere, the inertia of the system will be too great for noticeable damage to be done, but that does not make less urgent the need of a research programme directed to this end.

The implications of these considerations for the decisions that must now be made about the future of

supersonic transports on both sides of the Atlantic are clear but unexpected. In Britain and France, to be sure, the issue may be decided in the next few weeks if it turns out that the Concorde is not commercially viable for technical reasons. If that should happen, no doubt there will be a tendency to move ahead more slowly with the Boeing aircraft, which will simplify many problems. But whatever happens, governments—not merely those with taxpayers' money tied up in development programmes—should urgently consider whether the present structure of the airline business is that best designed to make full use of the technological benefits of the modern aircraft industry. As things are, with an international cartel arrangement on fares within the International Air Transport Authority (IATA), airlines are able to compete with each other only by embellishments of the services which they offer. Some airlines win customers by the sandwiches which they serve in flight. There is now a danger that the arrival of supersonic aircraft may be yet another artificial means by which airlines can compete among themselves for passengers. To be sure, the members of IATA can be relied on to agree among themselves on a surcharge for flights by supersonic aircraft, so that the pressure of competition will not be felt too severely by those airlines only barely able to stay in business as things are, but that will only mean that such advantages as there may be in supersonic flight are put even further out of reach than the working of supply and demand would ensure. What all this implies is that governments should try to ensure that vested interests in the supersonic aircraft should not exert an exaggerated influence on the pattern of air transport, and the way to do this is to replace the present rules within IATA by more flexible arrangements that will allow airlines to compete with each other not merely on service but on price. That is the common cause on which opponents and supporters of supersonic aircraft, Senator Proxmire not excluded, should conspire.

One Myth Less

AMONG the myths of modern times, none has endured so well as the belief that the power blackouts which crippled New York and much of the north-eastern United States on November 9, 1965, were followed nine months later by a surge in the birthrate in New York City. To be sure, in the middle of the silly season in 1966, it was only natural that newspapers should be eager to fan into flame reports that the numbers of births at hospitals in New York were then abnormally frequent. The *New York Times* has the doubtful distinction of having been first with the news, and Mount Sinai Hospital of all places is said to have been the hospital at which a normal day's natality of eleven was more than doubled on Monday, August 8, when there were 28 births at the hospital. Similar if less spectacular results were reported elsewhere, and various branches of the social sciences have since

been distinguished in reputation by statements such as that of the sociologist who said "the lights went out and people were left to interact with each other". Luckily the reputation of his craft has been in part redeemed by J. Richard Udrey of the School of Public Health, University of North Carolina. Mr Udrey has shown (*Demography*, 7, 325; 1970) that reports of an enhanced birthrate in New York are most probably accounted for by that part of the collective unconscious which supposes that dreadful things always happen when the lights go out.

The truth is that, as Mr Udrey shows, that the blackout in New York had no demographic consequences worth speaking of. He has compared the number of births in New York in the summer weeks of 1966 with those in earlier years. There is statistical evidence to show that 90 per cent of children con-

ceived on November 10, 1965, should have been born between June 27 and August 14 in the following year. And day-by-day records of births in New York City apparently show that in each of the first five years of the decade the numbers of births in the corresponding intervals accounted for between 13.9 and 14.1 per cent of all births in the year. As luck will have it, the same interval in 1966 accounted for 13.9 per cent of the year's total births. Comparisons of weekly averages for the first half of the sixties show that there was no significant difference between the pattern of 1966 and that of the preceding years.

Mr Udrey is realistic enough not to expect that his simple analysis will prevent all further talk of the demographic aftermath of the great blackout but that, of course, is an exceedingly passive point of view. The question he should be asking is whether power cuts could not be used deliberately, by sufficiently clever local authorities, as a means of regulating the population. For if, as it now seems, it may be possible to create among city populations the belief that there has been a massive increase in population simply by switching off the lights, may it not also be possible by switching off the lights every few days, to create among the populations of cities such as New York such a powerful conviction that the city is about to burst with people that nobody will dare bring children into the world? Is it too much to ask that Mayor John Lindsay, with all his present troubles, should be the first to try this out?

100 Years Ago

Many persons are, no doubt, under the impression that the deaf and dumb talk to each other by means of the finger alphabet; but the use of this pre-supposes a knowledge of the meaning of words and letters, which the deaf and dumb child can hardly be taught till intelligible communication has been established with it. Alphabetical speech is slow and clumsy, whereas the deaf mute speaks to his comrades as rapidly, if not as precisely, as we do by means of vocal speech. He uses a copious and expressive language of signs, indicating words and ideas by means of simple motions and gestures. This language has the advantage of being natural and universal. English, French, and German children to a great extent understand each other, and even a North American Indian would be able to talk with them all, it being a curious fact that many of the signs used by the Indian tribes are identical with those of the deaf and dumb schools of Europe; and Mr. Tylor states that a Sandwich islander and a Chinese both made themselves understood in an American deaf and dumb institution.

From *Nature*, 2, 350, September 1, 1870.

OLD WORLD

ENVIRONMENT

Message for Alarmists

"THOSE prophets of doom who predict the more bizarre kinds of human catastrophe and paint rather self-righteous pictures of scientists as irresponsible villains exploiting humanity to the point of disaster could well be doing their own (and our) cause a great disservice." With these words, Mr F. E. Ireland, Chief Inspector of Alkali Works in the UK, in the annual report of his inspectorate to the government (*106th Annual Report on Alkali, &c. Works*, 1969, HMSO, 50p), launched into an outspoken and remarkable attack on the swelling tide of alarmist utterances about the environment which he believes are founded more on emotion than on fact. The attack is remarkable both for its forthright nature and because it flies in the face of a public opinion that is well and truly roused.

One of Mr Ireland's responsibilities is to see that factories conform to air pollution regulations, and he therefore has a vested interest in seeing that the environment is cleaned up. One of his chief worries is that alarming predictions about pollution will have two undesirable consequences: there will be a flood of questions from an alarmed public which will waste the inspectorate's time, and, more important, "we may lose sight of the real dangers and dissipate our resources".

Two such prophecies which Mr Ireland singles out for attack are that carbon dioxide in the atmosphere will produce a greenhouse effect, resulting in an increase in the Earth's atmospheric temperature, causing the polar ice caps to melt and flood a great many coastal towns and cities, and that the formation of a belt of dust in the atmosphere will cut out some of the Sun's radiation, causing the Earth's temperature to drop. Both these theories are dismissed as mere speculation. There is no sign, Mr Ireland suggests, that the various physical features of the earth such as weather, temperature, position of the magnetic pole and so on, which "undergo regular long-term periodicity in fluctuation", are being disturbed by man's efforts "which are puny compared with nature's".

Mr Ireland also takes to task those who believe that the elimination of industrial sulphur dioxide from the atmosphere will signal an end to the pollution problem. "It is estimated", he says, "that man's efforts cause the emission to air of 120 million tons per year of sulphur dioxide, whereas natural causes by comparison are responsible for 600 million tons per year. Moreover, it is not the only acid-forming gas in the atmosphere." Fortunately, however, most of Mr Ireland's natural processes take place a long way from heavily populated areas where the sulphur dioxide would do much damage.

One thing which Mr Ireland makes clear is that he is as concerned as the next man that the environment should be kept as clean as possible, but what he really wants to see is a clear recognition of the tasks that lie ahead. In this regard, Mr Ireland takes the opportunity to blow his department's trumpet. British pollution control policies, he says, represent a continual advance by the workings of conscience and conciliation, so that "our achievements are

believed to have surpassed those of any other comparable industrial country". Despite this achievement, however, the chief tasks in Mr Ireland's estimation are to reduce domestic emissions, internal combustion engine exhaust gases, grit and dust and, notwithstanding natural process, sulphur dioxide.

NUCLEAR FUEL

Centrifuge Pulls in Partners

THERE may soon be two new recruits to the European centrifuge club, if proposals submitted to the Italian and Belgian governments earlier this month are taken up. Although official comment is still scarce, it seems clear that the Italian Government in particular has been attracted by the offer of joining the centrifuge scheme with Britain, West Germany and the Netherlands for the production of enriched uranium, and may soon be negotiating its way into the project.

Nuclear Safeguards

THE United Kingdom Atomic Energy Authority has now made public the steps which it has been taking in the past few years to devise instruments which can help with the automatic monitoring of the uses to which fissile material from nuclear reactors is put. The authority is one of several organizations engaged with the International Atomic Energy Agency in the development of techniques like this. Its particular interest is in the detection of the delayed neutrons which are given off after the fission of uranium or plutonium nuclei.

In one technique that has been developed at Aldermaston, 14 MeV neutrons are used for irradiated samples, usually consisting of uranium swarf pressed into pellets or plutonium fragments packed under pressure into cylindrical plastic containers. After irradiation, the proportions of the two different materials can be determined by standard radioactive techniques for the detection of delayed neutrons, six groups of which may be emitted with half lives ranging from a fifth of a second to 55 seconds.

This method works best for highly enriched materials. For the analysis of fissile materials in solution, the authority has been working on gamma absorption, either directly through the walls of piping or tubing or by the construction of special cells at suitable places in a plant. It appears that the disadvantages of using absorption through constructional piping are considerable. A specially designed absorptiometer incorporating a plastic scintillator has been found satisfactory for gamma absorption measurements and obviously has a future in various separation plants. The authority's work does, however, suggest that electrolytic methods involving the measurement of the electrolytic potentials due to particular ions in solution may in the long run be one of the more convenient techniques.

The possibility of having an enrichment plant in Italy is naturally one of the chief benefits the Italian Government could hope to reap, and the prospect seems to be enticing. The exact role of a Belgian presence in the project seems more obscure, but one body that is likely to be jubilant over the likelihood of a wider European agreement is the European Commission itself. One of the ticklish points about the centrifuge agreement signed in February was that Britain was not a member of Euratom, and that under the Euratom treaty member states have to submit to the commission any draft agreements involving non-Euratom organizations. One objection the commission may have harboured was that Britain may be in a position to bar other members of Euratom from access to the enriched uranium. If Italy and Belgium now join, even the technicality of this objection will become wafer thin.

A reminder that the enriched fuel business is not the only one with commercial attractions came last week with the announcement that the UK Atomic Energy Authority had secured a contract from the American Combustion Engineering Company for the conversion of uranium concentrate to uranium hexafluoride. The deal is estimated to be worth between £1 million and £1.5 million. The conversion to hexafluoride is a vital step in the path from rough ore to enriched fuel suitable for reactor consumption and is the stage prior to the enrichment process, whether by gaseous diffusion or by centrifuge.

The order has come at a good time for the Production Group of the AEA. The present production of enriched uranium at Capenhurst is not sufficient to keep the hexafluoride plant at Springfield, Lancashire, at full stretch, and the completion of the centrifuge, with its capacity of 200 tons of uranium a year, is still a long way off. The production group, which trades as a separate entity and would have been amalgamated with the Radiochemical Centre at Amersham as a new fuel company under the programme of the previous government, will purchase uranium concentrates from US mining companies, convert to hexafluoride at Springfield, and deliver the high purity material for use in American gaseous diffusion plants.

GERMANY

Poised for Aerospace Boom

A SUBSTANTIAL increase is expected to be announced shortly in the funds allocated by the Federal Government for projects in the German aircraft and aerospace industry. The Federal Ministry of Industry is seeking the approval of parliament for its plan to spend DM11,670 million (£1,348 million) during the five years to the end of 1974 for projects in the air and space industry, about three-quarters of which will be for military aircraft and equipment.

The Federal Government's support for space projects shows a dramatic increase. The present estimate for the five-year period to 1974 is put at DM2,624 million compared with DM1,419 million for the period 1962-69. Although the figures are still provisional, the Federal authorities seem confident that the German air and space industry will soon emerge from the brief lull occasioned by a drop in new military projects and that production will soon be rising steeply again. The turnover of the industry, which

employs nearly 50,000 people, was about DM2,000 million in 1969, although there is inevitably a fair margin of error according to the way in which the fringe areas of the industry are defined.

Military projects in which the Federal Government already has a large stake include the multi-role combat aircraft (MRCA), involving DM2,000 million, and the new trainer aircraft costing DM55 million. Among civil projects, the Federal treasury is contributing DM228 million to the development of the short-range VFW 614 aircraft and at least DM750 million to the European airbus, the A-300 B.

UNIVERSITY ENTRANCE

Oxford and Cambridge in Demand

THE demand for places at the Universities of Oxford and Cambridge shows little sign of slackening off. This year, the universities attracted more than twice as many men as they could accommodate and more than four times as many women. But, while the total number of applications for places at Oxford was slightly higher than that for 1969, the University of Cambridge attracted nearly 400 fewer applications than it did last year.

These figures, which have been published by the admissions offices at the universities (*Oxford University Gazette*, supplement to No. 3440, and *Cambridge University Reporter*, No. 4719), show that although the demand for places at Cambridge is still greater than that for places at Oxford, the traditional disparity in applications for each institution is beginning to disappear. Both institutions also continue to attract many more applicants for each place than do other universities—Dr Geoffrey Templeman, chairman of the Universities Central Council on Admissions, estimated that the number of qualified applicants who were chasing places in all British universities in 1968 outnumbered the places available by about 1.5 to 1.

Table 1. APPLICATIONS AND ACCEPTANCES FOR OXFORD AND CAMBRIDGE 1970

	Oxford		Cambridge	
	Applica- tions	Accept- ances	Applica- tions	Accept- ances
Men:				
Arts	1,465	756	1,687	828
Social Sciences	792	355	764	343
Science	1,728	813	2,451	1,222
Total	3,985	1,924	4,902	2,393
Women:				
Arts	1,041	275	1,097	168
Social Sciences	197	51	150	19
Science	554	167	629	134
Total	1,792	493	1,876	321

The educational and social background of students accepted for places at Oxford and Cambridge also differs significantly from those accepted by other universities. Fifty-six per cent of the students accepted for places at Oxford, for example, came from independent and direct grant schools, compared with 43 per cent from maintained schools, while for Cambridge the figures are 56 per cent and 41 per cent respectively. There is some indication, however,

that the share of the acceptances which go to students from independent and direct grant schools has been falling slowly during the past few years, while that for students from maintained schools is on the increase.

Oxford and Cambridge also do not seem to share the difficulty found by most universities in attracting students to study science and technology—the demand for science places among the men who applied for places next October was not significantly less than that for other subjects. Both universities also experienced a drop in the number of applicants for arts subjects, compared with applications last year, while the number of applications for places in science at Oxford increased by 300.

UNIVERSITIES

No Change in 1968

THE University Grants Committee this week published the latest pamphlet in its series of statistics of education. The statistics, although they are two years old, make interesting reading and they indicate that the broad trends in student numbers and university finance which developed during the early 1960s showed little signs of change in 1968–69 (*Statistics of Education: Universities, 1968*; HMSO, £2.40).

The total number of students engaged on full time courses at British universities in 1968–69, for example, increased by 5.7 per cent compared with the previous year to 211,485. The number of full time teaching and research staff, on the other hand, increased by only 2.8 per cent, from 25,353 in 1967–68 to 26,067 in 1968–69. This caused the staff/student ratio to increase from 7.9 : 1 to 8.1 : 1. Looked at on their own, these figures seem to indicate that the government's desire to see teaching costs reduced in the 1970s was already being realized two years ago. But the figures must be seen in the light of increases in the numbers of students and staff in the previous year. In 1967–68, the number of students increased by 8.5 per cent while the number of staff increased by 11.5 per cent; the staff/student ratio has in fact remained constant at about 8 : 1 since 1958.

The exodus from the sciences into the arts and social sciences also showed little sign of easing off in 1968–69. The proportion of students studying science based subjects, at 55.8 per cent, was 0.7 per cent lower than in the previous year. Between 1965–66 and 1968–69, the proportion of students taking arts subjects increased from 41.9 per cent to 44.2 per cent, mirroring the decline in the proportion of science-based students. By far the most striking comparison, however, is that 23 per cent of the men were studying engineering and technological subjects, while only 0.8 per cent of the women students ventured into this field.

In 1967–68—the latest year for which figures are available—the universities received £216.6 million, chiefly as a recurrent grant from the Exchequer (£157.8 million) for recurrent expenditure and a further £78.4 million for capital expenditure. Salaries swallowed up more than 40 per cent of their recurrent expenditure, and departmental expenditure met by research grants took a further 11 per cent. The total grant to the universities therefore increased by 8.4 per cent, while student numbers in that year increased by 8.5 per cent.

IRELAND

Education Renaissance in Galway

A SIGNIFICANT milestone in the 120 year history of University College, Galway—and indeed in the history of higher education in Ireland—has recently been passed. A project consisting of a two-storey science building to house departments of biochemistry, chemistry and physics linked with a four-storey library block was set in motion earlier this month when Dr M. O. Knuthail, the college president, signed a contract worth £2 million with John Sisk and Sons Limited, a local building firm.

A grant for the development of University College, Galway, was announced at the end of 1967 by the late Mr Donagh O'Malley, then Minister for Education, and it will provide eventually for a single campus of some 3,000 acres, accommodating 6,000 students. The overall cost is estimated to be £10–£12 million. The first stage of the project, the science building and library, should be completed in time for the 1973–74 session.

The University of Galway project is at least tangible evidence that Ireland is emerging from a period of stagnation in higher education. A report published earlier this year by the Organization for Economic Cooperation and Development drew attention to the slow development of higher education, and in particular to the lack of science and technology students—projections indicated that there should be about 19,000 students enrolled in Ireland's universities in 1970–71, of whom only 20 per cent are expected to study science and technology. The OECD report repeatedly pointed out that educational planning authorities have given insufficient attention to higher education during the 1960s.

METEOROLOGY

Next Year's Forecast

RELIABLE weather forecasts for up to a week ahead are promised by the Meteorological Office as one of the benefits of the new computer it is installing next year. And, according to the report of the office for 1969 (HMSO, London, 13s), daily forecasts should include the amount and distribution of rainfall that is expected over Britain and western Europe. The computer is to be an IBM System 360/Model 195—the largest available from IBM—and as well as putting advances in mathematical modelling techniques into forecasting practice, it will be used to continue research into the evolution of large scale weather systems.

One prerequisite for better and quicker forecasting is a fast telecommunications system to deal with data from stations in Britain and overseas and with the growing quantity of information from weather satellites. Here the Meteorological Office is also bringing in more computers: the first stage of the automation of its telecommunications centre, which should be completed later this year, will establish it as a principal link in the Washington–Moscow trunk circuit of the World Weather Watch, and during the next few years the whole of the British data-gathering network will be modernized. This updating will include the setting up of an automated radiosonde system at sixteen

weather stations, and operational trials of a number of completely automated stations.

Simulating air movements in the laboratory. *a*: the flow pattern at the top of a rotating annulus of water; *b*: contours at intervals of 200 feet (—) and isotherms (---) at the 500 mb level for 0400 h on October 12, 1945. (Crown copyright. Published by permission of the Controller of HMSO.)

On the research side, laboratory models of atmospheric motion have been helping, sometimes quite graphically, to show how complex movements on a large scale can be caused. The technique that a team under Dr R. Hide has developed uses rotating cylindrical pans of water, heated at the circumference and

cooled at the centre to simulate the temperature gradient between the pole and the equator, and the patterns that are revealed by a suspended indicator such as aluminium powder can often resemble the familiar shapes of the weather map. There are, for example, disturbances which resemble cyclones and fronts—a fact which implies that the condensation of water vapour is not one of the most important factors controlling the occurrence of these phenomena in the atmosphere. If the heat source is moved around the circumference of the pan, the daily cycle of solar heating can be simulated, and the ensuing motions are likely to be helpful in understanding how the atmospheres of other planets behave. Even the apparent shearing motion at the edges of the Great Red Spot of Jupiter seems to have its parallels in the model.

ANTIBIOTICS

Swann Implemented

THE British Government is to enforce from next March the classification of antibiotics into feed antibiotics, which can be mixed with animal foods to promote better growth, and therapeutic antibiotics, which cannot be given to animals without a veterinary surgeon's prescription. This separation was the chief method for reducing the risk of transferring resistant microorganisms from animals to man recommended by the Swann committee last November (see *Nature*, **224**, 835; 1969). In deciding which antibiotics to ban from feeds the government has largely followed the views of the committee.

Penicillin, chlortetracycline and oxytetracycline thus become "therapeutic", and the retail sale or supply of feeds containing them will be unlawful except on prescription or with written veterinary authority. Tylosin, most of the sulphonamides and four nitrofurans will be available only on prescription. Here, sulphaquinoxaline and sulphanitran will, in spite of Swann, still be allowed in feeds for poultry to provide resistance to coccidia, a group of protozoans which occur as parasites in the digestive system. The government is apparently happy that the use of these two sulphonamides will not conflict seriously with the Swann criteria for feed antibiotics: that they should be of economic value, have little or no therapeutic application and not lead to the development of resistant strains of organism. Sulphanilamide will also be available without prescription, but only as a surface wound dressing for animals.

The approved feed antibiotics will then be flavomycin and virginiamycin, which are to be officially classified as such in time to be freely available before the other antibiotics are outlawed. A third feed antibiotic, zinc bacitracin, has already been passed for use in promoting growth.

RABIES

Dogs and Cats Reprieved

MR JAMES PRIOR, Minister of Agriculture, and Mr Gordon Campbell, Secretary of State for Scotland, wasted no time in accepting the chief recommendations of the interim report of the Committee of Inquiry

on Rabies (see *Nature*, **227**, 765; 1970). It took them just one week to digest the report and to announce that the complete ban on the import of domestic dogs and cats will be lifted on September 16. They have also decided that a quarantine period of six months is sufficient provided that imported animals are vaccinated twice during their stay in quarantine kennels.

One of the committee's recommendations which will not be implemented, at least for the time being, is that dogs and cats should be vaccinated before import. This recommendation, the Ministry of Agriculture suggests, requires further exploration because it would necessitate changes of procedure in the country of export. Should rabies break out in a quarantine kennel, the period of quarantine for other animals in the kennel will be extended for as long as the ministers think fit and no more animals will be admitted to the kennel concerned. This precaution is presumably dependent upon the committee of inquiry's final report on the isolation of animals inside kennels.

The 850 dogs and 150 cats which are at present in quarantine and which will have completed nine months in kennels by September 7 can look forward to an early and painless release—they will be allowed home without vaccination on that date. The remainder of the dogs and cats in quarantine kennels—about 1,100 dogs and 200 cats—will be only a little less fortunate. They will have to be vaccinated twice, and will be returned to their owners from September 30 onwards, as soon as they have completed their nine months' stay in kennels. As far as other canine and feline animals are concerned, the committee has not made up its mind whether or not the ban on their import should be lifted and the ministers have accordingly decided that the ban should stay. But any of these animals which have already served nine months in quarantine can be freed from restrictions on September 7.

AGRICULTURAL SCIENCE

Missed Targets

by our Soviet Correspondent

SOVIET agriculture is lagging behind the target proposed for it in the 1966–70 five-year plan. This was pointed out in no uncertain manner at the July plenum of the Central Committee of the CPSU, and was officially disclosed last week by F. D. Kulakov, secretary of the Central Committee, during the opening speech of the Lenin All-Union Academy of Agricultural Sciences. The Academicians of the LAAAS pointed out that the development of agriculture is inseparable from the progress of science, and that the facts presented at the July plenum call for the development of improved methods of tilling the soil, for new, high yielding strains of crops and livestock, and for new means, especially biological ones, of protecting plants. The need for new and more effective technology leading to the complete mechanization of agriculture and stock-rearing, and for "economically based recommendations" for the agricultural industries on a regional, rather than an all-union basis were also emphasized.

This meeting comes at a significant point in the history of Soviet agriculture—shortly before the

Twenty-Fourth Party Congress (now scheduled for next spring), and on the threshold of a five year plan. If the planning authorities draft their directives in accordance with the proposals which arose from the discussions at the conference, the forthcoming plan should yield results that are considerably more satisfactory than the last.

HOVERCRAFT

Hover-Over from Canada

AN overseas firm using British hovercraft patents under licence has just put its home-developed hovercraft on the English market. The specially formed company, Canahover Ltd, a subsidiary of the Ottawa Bogue Electric Manufacturing Company, is currently demonstrating the Hover-Over on the Thames and a freighter version is on view at Ontario House, Charles II Street.

The Hover-Over can also be used as a two-seater sports vehicle or as an amphibious runabout. The single-seat freighter version has 600 lb. of payload available in a well behind the driver's seat and it also has a future as a seismic or general survey craft, while the two-seater could be used for waterway patrolling. The price quoted is between £2,300 and £3,000—there is some uncertainty about carriage costs from Canada—and there is no import tax.

The craft is 16 feet by 7½ feet with a 16 inch skirt of all-Canadian design. It is powered by three Rockwell 2-stroke air-cooled engines originally developed for the 'sno-mobiles' now so popular during the Canadian winter. It is very robust and will be able, it is claimed, to travel over water, mud, snow and sand. A great advantage is that this engine has a very narrow range of operating temperature—in previous small hovercraft most of the engine trouble encountered has been due to the cold-water dousing of an engine running very hot. Altogether \$2 million (Canadian) has been invested in modifying the engine over a period of two and a half years.

The Hover-Over can reach 50 knots under smooth conditions and cruises at 35 knots. It is said to be very economical of fuel. Two hundred craft have been sold in North America since it was put on the market there last spring.

Its most direct competitor on the English market is the Hoverhawk made by the East Anglian firm of Hover-Air. This has been powered in the past by a two-stroke motor-cycle engine. From the current demonstrations the Hover-Over seems marginally more manoeuvrable.

The sales drive for the Hover-Over has started in London because of its central position for marketing both in Europe and the Middle East. The company has its eye in particular on Central and Eastern European waterways, and on the oil industry's activities. All the oil companies, it is pointed out, have London offices.

Mr Griffen, Hover-Air's general manager, considers that the British hovercraft industry will have much bigger earnings in North America through selling licences and collecting royalties from North American built vehicles than in direct sales. Last winter a contract for 4,000 Hoverhawks was said to have been placed by Canadian interests.

Miscellaneous Intelligence

THE irony of the new appointment as head of Space Division at the Ministry of Technology on the translation of Mr Richard H. W. Bullock to a deputy-secretaryship could hardly be more complete. It goes to Mr A. Goodson who for the past three years has been on loan to ELDO, and what is more, as Director-General of Financial Affairs. The main thrust of the policy that Mr Bullock has been responsible for pursuing was to prove the non-credibility of ELDO and to withdraw Britain's financial support from it. Can this appointment be taken as the climax of the policy's success?

THE story of how an ornithological fraud of almost Piltown dimensions was foisted on British scientists in the 1900s with effects to this day is revealed in the current issue of *British Birds*. 595 rare bird species that had never before been recorded in Britain were reported over a period of years by a Sussex taxidermist called Bristow. He claimed to have shot them on the Hastings coast and in spite of the extraordinary degree of coincidence involved, the 595 "Hastings Rarities" were accepted by the establishment. A number of them were even included in the 1952 definitive *Check List of the Birds of Great Britain and Ireland* on Bristow's evidence alone.

Some British bird men were increasingly suspicious of the Rarities but could not account for how Bristow had obtained fresh specimens of foreign birds. Robert Coombes now tells how he chanced to meet the man who smuggled in the birds from the Persian Gulf, the Baltic and the Mediterranean before the First World War. He was a ship's steward called Parkman, and, on a commission from his brother in England, he shot or bought wild birds at his ports of call and kept them on ice on the voyage home. There he handed them over to his brother who, he knew, disposed of them at Hastings "to a man called Bristow".

Almost equally extraordinary is the time it has taken to get the record straight. Mr Coombes learnt about the bird smuggling route in 1939, when he was importing some geese specimens from Persia, which Parkman, still on the Middle East run, cared for en route. In 1947 when Coombes was an officer of the British Ornithologists Union he mentioned the matter to the then President, Sir Norman Kinnear, who told him to keep quiet. This he has reluctantly done for another 23 years.

THE Soviet journal *Khimia I Zhizn* claims that Soviet biologists have discovered that human beings exhale a variety of obnoxious substances, including "hydrocarbons, alcohols, ammonia, formic and acetic acid, formaldehyde and acetone". It is no wonder that all the talk about cleaning up the environment seems to have had little effect.

THE prize for the most amusing scene at the meeting of the International Astronomy Union held in Brighton last week must surely go to the opening celebrations. Much to the embarrassment of the British astronomers, the band of the Coldstream Guards launched into "Rule Britannia", and about 1,000 astronomers from all over the world joined in the chorus. The astronomers were later treated to a rendering of "Twinkle, Twinkle, Little Star".

Pulsars Explained, Craters Named at IAU

from our Special Correspondent

Brighton, August 25

It might have been expected that the general assembly of the International Astronomical Union that opened in Brighton last week would have been dominated by pulsars. After all, they were unknown at the last general assembly three years ago. But the IAU Symposium held at Jodrell Bank at the beginning of August seems to have preempted the debate (for a report see *Nature*, **227**, 651; 1970). That is without counting the resourceful Professor Vitaly L. Ginzburg, of the Lebedev Physical Institute (Moscow), however. Professor Ginzburg was not at the Jodrell Bank meeting, and he arrived at Brighton with a theory of the pulsar radiation mechanism based on the maser emission process to explain the extraordinarily high brightness temperatures of 10^{23} K that are recorded. "Maser mechanisms", he says, "are quite capable of explaining all the peculiarities of the radio emission of pulsars." People were saying, however, that if Professor Ginzburg had seen the polarization measurements that were presented at Jodrell Bank he would not have been so confident.

Now that nobody is doubting that pulsars are rapidly rotating neutron stars, the discussion has centred on the radio emission process. By comparison, the questions of how the neutron stars are formed, and what they are like inside, are receiving less attention. The reason seems to be the feeling that not enough is known about the physics of matter at the densities of 10^{12} grams per cubic centimetre, and more, that are believed to exist inside neutron stars. But the observational material that has been built up over the past two and a half years on the radio, optical and X-ray pulses is for the moment just as hard to disentangle. Most attention is being given to two facets that people intuitively believe must hold the key. First, the way that the angle of the linear polarization often rotates throughout the duration of a pulse at a rate that is characteristic for each pulsar is felt to be important. Second, at least five of the fifty-five pulsars so far recorded seem to contain a system of weaker pulsations at rates of 10 to 100 per second superimposed on the main pulses. T. W. Cole from Sir Martin Ryle's group at Cambridge reported that in the case of CP 0808, the speed at which these subpulses drift through the main pulse follows a sawtooth pattern. But so far nobody has been able to work the polarization results and the subpulses into a theory of pulsar emission that their colleagues will accept.

It was inevitable that the second talking point at Brighton should have been the new data about the Moon. Again, with the Apollo geological and seismological data entirely new since the last general assembly in Prague, there has been a lot to talk about. Yet it is odd that what has captured people's imaginations has been the naming of the craters on the far side. A working group of four to select the names was appointed at the Prague meeting, and their list was expected to be approved on the final day at Brighton. Professor Donald Menzel (Harvard College Observatory), chairman of the group, described the work as

"very interesting but arduous labour". His colleagues were Professor M. Minnaert (Utrecht), Professor B. Levin (Moscow) and Professor A. Dollfus (Paris).

They had wanted the list to be as international as possible and national academies of science were asked to submit names. The 1,200 names received were then pared down to a list of 513 that the group felt were the most distinguished, representational and truly international. One idea which the group was keen on was to assign the names in alphabetical order from the north to the south pole. Aesthetic sense prevailed, fortunately, and instead the names were divided among five categories of distinction, and the craters among five categories of size. Names were assigned to craters in the corresponding distinction category by drawing lots.

Forty-nine British people are listed, chiefly scientists but including Geoffrey Chaucer and H. G. Wells. It was a nice touch that there should be a crater named after Sydney Chapman who died earlier this year. Other British names on the list include Sir Edward Appleton, Robert Boyle, William Bragg, Sir John Cockcroft, Sir Alexander Fleming, Oliver Heaviside and Sir Harold Spencer Jones. But the New Zealander Lord Rutherford had to be omitted because of the possibility of confusion with a crater Rutherford on the near side. The same happened to Born because of confusion with Bohr.

A dozen names of living people have also been assigned craters, setting something of a precedent. The three Apollo 11 astronauts have been given small craters a few kilometres across near the landing site in Mare Tranquillitatis, and the Apollo 8 astronauts, the first to fly behind the Moon, have craters on the far side. To redress the balance six living Soviet cosmonauts have been named. The names of the American astronauts killed in the launch pad fire have been given to small craters near a far side feature to be called

University of Sussex, where part of the assembly is taking place. Designed by Sir Basil Spence, Bonnington and Collins.

Apollo and the names of dead Soviet cosmonauts are given to features near Mare Moscovense. But the name of Yuri Gagarin, killed in an air accident in 1968, has been given to one of the larger features on the far side.

As *Nature* went to press the list of names had not so far caused any international ructions. Objections had been raised to about half a dozen names on the list by the IAU Commission on the Moon, but these it seems were trivial points rising, for example, from possible confusion when names were assigned to small craters within larger named ones. In these cases the working group agreed to move the names to other locations.

Debate about the scientific data on the Moon that the Apollo programme has produced seems to be centring on the age measurements for the lunar material, and on the seismic data. Ages as great as 4.5×10^9 years have been assigned to some of the samples, and the debate appears to be narrowing down to a discussion of precisely what are the zero points of the conventional dating techniques. The seismologists, on the other hand, are deciphering the 250 natural events that have so far been recorded, and they seem to have been remarkably successful. It has been possible to identify a class of moonquakes which occur when the Moon is at perigee, presumably due to tidal forces in the interior, and to distinguish these from events caused by meteorite impacts. The meteorite events have been attributed to meteorite masses of a few kilograms, and the rate nicely fits the Hawkin's meteorite distribution curve. But the burning question which Professor M. Ewing (Columbia), one of the lunar seismologists, was at a loss to explain was why the traces from a few of the events are an almost perfect match. "I have never seen terrestrial earthquakes that match so well", Professor Ewing said.

Secrecy and Little Green Men

AT Brighton last week Professor V. L. Ginzburg, of the Lebedev Physical Institute, met Dr A. Hewish of the Mullard Radio Astronomy Observatory for the first time since the discovery of pulsars was announced in *Nature* two and a half years ago (217, 709; 1968). Professor Ginzburg had been staying with Dr Hewish at Cambridge while the Cambridge group was grappling with the problem of the origin of the regularly pulsing signals. But Ginzburg, now one of the foremost Soviet theorists on the pulsar problem, was not told of the discovery. The omission rankled, Ginzburg admits, when he returned to Moscow and saw the first report of pulsars in *Nature*. But at Brighton last week Ginzburg agreed with Hewish that the Cambridge group were right to keep the signals a secret until the experiments to check whether they were coming from extra-terrestrial life had been completed. Dr Hewish and the Cambridge group are forgiven, Professor Ginzburg says, now that he (Ginzburg) realizes that the British astronomy community was not party to the secret either. Dr Hewish explained that if the discovery of pulsars had been reported any earlier the Cambridge observatory would have been overrun by the press, making work impossible.

RADIO ASTRONOMY

Case of the Unidentified Line

ANOTHER addition to the growing list of molecular species that have been identified in interstellar space is expected soon. L. E. Snyder and D. Buhl reported to the IAU meeting on interstellar molecules on Monday that a new line has been detected that is so far unidentified. The line has a rest frequency of $89.190 \text{ GHz} \pm 2 \text{ MHz}$ and has been seen in four, probably five, sources. It was first picked up while Snyder's group was recording a line of HCN using the 36 ft telescope of the National Radio Astronomy Observatory at Kitt Peak, Arizona. The unidentified signal appeared in the upper sideband while the line due to molecules of HCN containing the carbon isotope ^{13}C was being observed in the lower sideband. Snyder said that he is "fairly convinced" that the line is molecular. And it is unlikely to be a Doppler-shifted HCN line—that would require a radial velocity of 1,690 km per second, an order of magnitude greater than the velocities that have been measured in interstellar clouds. The unknown molecule has been named X-ogen by Snyder and his colleagues and it has been recognized in W3, Orion A, Sagittarius A, W51, and probably in L134.

It was only two months ago that Snyder's group reported the detection of interstellar HCN. So far this molecule has been detected at 88.6 GHz (3.4 mm) in six sources, W49, DR21, Orion A, W3, W51 and Sagittarius A. It is also pleasing that the line corresponding to substitution by the isotope ^{13}C has been detected—the line that was being observed when X-ogen was discovered. The abundance ratio $^{13}\text{C}/^{12}\text{C}$, significant for theories of nucleogenesis, can then be determined.

The list of molecules that have been detected in the past year or so makes interstellar space sound like an organic chemistry laboratory. Professor C. H. Townes (Berkeley), who as much as anybody inspired the search for these molecules, pointed out at the meeting that a lot of hard work had been unsuccessful. Although ammonia, formaldehyde, and even cyanacetylene (HC_3N) have been detected, some simple molecules that might have been expected to be present because of their stability have not been found, for example, $\text{H}_2\text{C}_2\text{O}$. SiO , SO and H_2CO_2 have been looked for reasonably hard, but not found. One molecule which Townes predicted would be detected before long was NO. But he admitted that he could give no convincing reason why the molecules should be present to the extent that they are, although he agreed that conditions in the dark clouds where the molecules are found are likely to be the most favourable.

It was obvious from the meeting that the molecules are a nice source of surprises. Why, for example, should the abundance ratios $^{13}\text{C}/^{12}\text{C}$ and $^{18}\text{O}/^{16}\text{O}$ obtained from measurements of the isotopic variations of formaldehyde (H_2CO) disagree with the ratios observed in stars, and instead be more like terrestrial abundance ratios? What makes the H_2O line detectable, when work with very long base lines shows that some of the sources are less than one astronomical unit across? Amplification by the maser process is assumed. And why is the formaldehyde line seen in absorption when there is no continuum source in the background apart from the 3K isotropic radiation? In this case, some kind of maser process in reverse is suspected.

NEW WORLD

All Change at the Top

from our Washington Staff

DR LEE DUBRIDGE, Science Adviser to the President for the past few years, startled the establishment last Thursday with the announcement of his resignation from the end of August. He will be succeeded by Dr Edward E. David, a computer engineer from the Bell Telephone Laboratories. Dr DuBridge's departure from the White House will be accompanied by other important changes. At the National Science Foundation, the post of deputy director has at last been filled, again by an engineer—Professor Raymond L. Bisplinghoff, dean of the school of engineering at MIT. In the past few days it has become known that the successor to Representative Emilio Q. Daddario, chairman of the Subcommittee on Science, Research and Development, in the House of Representatives, will be Mr John W. Davies, the most senior of the six Democrats on the subcommittee.

The departure of Dr DuBridge will have the most immediate effect. He said last week that he had always had "a horror of staying at any job past reasonable retirement age". There is no doubt of the affection with which he is held in Washington, where he has been highly respected. It is also widely appreciated that the best time in which to be Science Adviser to the President is when expenditure on research and development is growing quickly, for then there is a good chance that the extra funds will be supposed to have been conjured up by the Science Adviser himself. From this point of view, Dr DuBridge has been unlucky, but his spell in office has also been marred by the muddle over the effects of the Mansfield Amendment on the pattern of federal research expenditure—effects that could have been anticipated. At the end of last week, Senator Mansfield went out of his way to emphasise that he had no personal quarrel with Dr DuBridge on this score.

Dr David is a Bell Labs man to the core. He moved there from MIT in 1950 and worked for more than a decade on underwater acoustics. Since then he has been engaged on computing science and has also played an important part in developing the high school curriculum intended to introduce young people to a sense of the importance of technology.

The appointment of Professor Bisplinghoff as deputy director of the NSF also raises new problems, for the post that he will occupy was only created two years ago and has not previously been filled. In an attempt to strengthen the foundation's hand in the Administration, Congress argued that it should have a deputy director and four assistant directors all of them appointed by the President. The four assistant directors

are already at work (see *Nature*, **226**, 105; 1970) and no doubt the deputy director would also by now have been at work for some time if the first choice for the post, Professor George Hammond, of the California Institute of Technology, had not blotted his copybook in June by speaking out against the Cambodian operation. There remains, however, some confusion about the precise function of the men now serving as assistants and deputy directors. With the National Science Board brooding over the foundation's work, does it really need six highly paid administrators to spend a mere \$500 million?

Dr Bisplinghoff has a NASA background, having been associate administrator for advanced research and technology from 1963 to 1965 and special assistant to the then administrator, Mr James Webb, for a further two years. More recently, Dr Bisplinghoff has been the chairman of a working party intended to advise the Administration on supersonic air transports. He is known to take the line that the SST would be a fine thing if its noise could be kept within bounds.

In the long run, the appointment of Representative Davies as chairman of the subcommittee on Science, Research and Development may turn out to be the most important of all the changes. Mr Daddario has for several years exercised a powerful influence on science policy, chiefly by making himself one of the few people

No Budget Yet

THE National Science Foundation is one of several agencies whose budgets for the current year have been snatched away by the President's veto on August 11 of the independent offices. On the same date, President Nixon also vetoed appropriations for the Office of Education. Both bills between them included roughly \$1,000 million for work not originally spelled out in the Administration's budget—\$453 million extra for education and \$451 million extra for the independent agencies. Although the National Science Foundation stood to gain \$9.6 million above the Administration's request for \$513 million, what seems to have stuck in the Administration's throat is the extra \$300 million appropriated by Congress for urban development. The next step will be for Congress to devise a more acceptable bill and there is a chance that this will find its way through Congress in the next few weeks.

in Congress who understood what the Administration was doing. Towards the end of his reign—Mr Daddario is almost certain to be elected governor of Connecticut in November—he has been influential enough to develop the legislation within which the NSF now operates. In the past few months, Mr Daddario has also lent his enthusiasm to doubtful projects such as that for setting up in Congress what he calls an Office for Technology Assessment.

Representative Davies is known to share Mr Daddario's enthusiasm for a stronger National Science Foundation. He is an amateur astronomer and holds a pilot's licence. His succession will not finally be assured until after the election in November, although there seems no doubt that he will be returned by his district in Georgia.

CBW

Geneva Protocol at Last

WITHIN hours of the scuttling of the old Liberty ship LeBaron Russell Briggs with more than 10,000 disused nerve gas rockets on board, President Nixon last Thursday sent to Congress his proposal that the Geneva Protocol on the use of chemical and biological weapons should be ratified. This step has been on the cards for the best part of nine months, ever since the Administration conceded that the case for including these materials in the arsenals of the twentieth century had become irrelevant. By all accounts, the delay has been brought about partly by the need to work out a policy on the use of tear gases and defoliants, materials used not merely as agents for the restoration of civil order but also as military weapons of a kind, as in Vietnam. The compromise which seems now to have been arrived at is that the United States Government has accompanied support for the Geneva Protocol with a declaration that tear gases (especially CS gas) and defoliants will be excluded from the provisions of the protocol, but that these materials will not be used without express permission from the White House after the ending of the Vietnam War. It remains to be seen whether those in Congress who are asking for a prohibition of the use of military appropriations for chemical defoliants will be able to dislodge this carefully calculated position.

The Geneva Protocol, which prohibits the "use in war" of chemical and bacteriological weapons, was first negotiated within the League of Nations in 1925 and has been ratified by 85 nations. The unwillingness of the United States to ratify the declaration has always been regarded as one of its more obvious defects. The President's message to Congress last week reserves for the United States the right to use chemical weapons if these should be used in war by either an ally or an adversary. Similar reservations have been made by many of the other nations which have ratified the protocol, the Soviet Union, the United Kingdom and France included. On the other hand, the recommendation by the Administration to Congress goes further than the position of many of the other countries which have ratified the protocol in suggesting that bacteriological weapons will never be used, whatever other countries may do. In an accompanying document, Secretary of State Rogers also makes it clear that the

United States Government considers that toxins, however manufactured, will be considered as biological weapons and not chemical weapons. In this and other ways, the position of the United States on chemical and biological weapons has now been transformed within the short space of a year. Controversy remains about the use of chemical agents in Vietnam, but the fact that the new position seems to have been reached after a hard-headed appraisal of the military inutility of these materials as weapons is not considered a disgrace.

SUPERSONIC TRANSPORT

Senator Proxmire Takes Off

THE Subcommittee on Economy in Government, in the person of Senator William Proxmire, last week launched an attack on supersonic aircraft, Anglo-French and American alike, so carefully contrived to prevent them reaching commercial service that it may have the effect of rallying support in their favour. One of the weaknesses of Senator Proxmire's position is that his subcommittee's report on the supersonic aircraft project has already been repudiated by two of the nine members—Senators John Sparkman and Stuart Symington. Another is that the witnesses who gave evidence at the hearings on which the report was based were notable for the absence of staunch defenders of the SST. (Officials of the Boeing Company, now building the supersonic prototypes, declined to appear.) In a dissenting statement accompanying the Proxmire report, one member of the subcommittee, Representative Clarence J. Brown, says that "if the joint Economic Committee had been advising Queen Isabella, we would still be in Barcelona waiting to prove the world round before daring the Atlantic".

The effectiveness of Senator Proxmire's attack on the SST project should be known in the next few weeks, when the Senate is due finally to vote on the proposal to include \$290 million for the development of prototypes in the budget appropriation for the Department of Transportation. There seems very little doubt that the vote this year will be closer than in the past. In the past few weeks, there have also been signs that the Administration is more ambivalent than ever about the virtues of the SST, chiefly because of the difficulty of estimating the effects of supersonic aircraft on the environment. In circumstances like these, external developments could have an important influence on the United States programme—if the performance of the Concorde in its impending series of trials should turn out to be far below specification, for example, Congress would probably decide to save \$290 million.

The subcommittee's case against the SST is that the social costs outweigh the potential benefits of supersonic civil aircraft, that the project is neither sufficiently radical to carry the technology of flight further forward nor so prestigious as to add to the international reputation of the United States, and that the Anglo-French Concorde project is not a serious commercial threat to the United States aircraft industry.

There has been a steady stream of argument in the past few years about the effect of the SST project on the United States economy, internally and externally. The Proxmire subcommittee now comes out firmly with the view that the effect of the project on the level of

employment will be unimportant—at the public inquiry during May, the chairman and one of his witnesses, Representative Henry Ruess, were fully agreed that a project costing \$1.3 million (up to the end of the prototype phase in 1973) and providing some 20,000 jobs at the Boeing plant at Seattle would be a needlessly expensive way of mounting a public works programme. Mr Ruess was the first of those giving evidence to the subcommittee to ask that the Federal Aviation Agency should publish the regulations on aircraft noise that will have to be satisfied by supersonic aircraft even before the first of the supersonic transports has flown. If this were done, Mr Ruess argued in May, “the rules . . . will ban the Concorde from this country. With the Concorde effectively banned from the profitable transatlantic market, it could no longer be considered a threat to the US aircraft industry or to the US balance of payments. And with the Concorde out of the competitive picture, the way is clear to call a halt to the SST.” Representative Ruess went on to say that the British and French governments had both been given a chance, a year ago, to “negotiate a mutual slowing down of the SST race”, and that it would be better to provide the financial assistance that Boeing needs by giving the company contracts “to improve our environment rather than destroy it”. He called the SST an “environment despoiling superplane for the jet set”.

The technical case against the SST recited by Senator Proxmire is based on evidence given by Richard L. Garwin, a physicist with IBM who has made a study of the SST project. He argued in May that successive amendments of the contract between the Boeing Company and the Department of Transportation have degraded the performance expected of the SST and that, for example, take-off noise from the aircraft was set at 93 PNdB (perceived noise decibels) in January 1967, but was now expected to be 110 PNdB. With the 125 PNdB of airport noise which might now materialize, the noise pressure at take-off of a supersonic transport could now be expected to be equivalent to the simultaneous departure of 50 jumbo jets. Mr Garwin provided Senator Proxmire with grist for his mill by pointing out that the contract between the US government and the Boeing Company provides no protection for the government against increases of cost, and that there is no assurance that the step from the end of the government's obligations under the contract (in which two prototypes will log 100 hours of flying time) to the commercial operation of the SST will be bridged by private funds. Senator Proxmire's views on the Concorde, chiefly that technical difficulties and inherent defects of design will prevent the aircraft being a commercial threat, are based on evidence to the committee by Miss Mary Goldring, business editor of the *Economist*.

The subcommittee has almost brushed aside the evidence provided in May this year by the two principal witnesses for the Administration, Mr James M. Beggs, Under Secretary of Transportation, and Dr Russell Train, chairman of the Council on Environmental Quality. Mr Beggs was quick to defend the economic prospects of the SST project, saying that the US Government would get its money back if 300 SST machines were sold commercially, and that there are at present reasonable prospects of sales of 600 aircraft. He also claimed that much could yet be done to reduce

the impact of the noise of the SST. Dr Train's evidence might in ordinary circumstances have carried even greater weight, for he asked that “we do not pursue technology for its own sake”, went on to express doubt about the feasibility of reducing the noise produced by the SST to acceptable levels but suggested that the present development programme should be continued up to the point at which a sensible decision could be made. The difference between Dr Train and Senator Proxmire is, of course, that the pressure to save money is now being felt more acutely by legislators than by government officials.

INTERNATIONAL COMMUNICATIONS

Keeping Cables Alive

THE American Telephone and Telegraph Company has made to the Federal Communications Commission what amounts to a plea for some kind of balance between telecommunications satellites and submarine cables. AT&T thus becomes the first of several organizations to respond to the request of the FCC last June for opinions likely to be of use in the working out of long-term policies for international telecommunications.

One of the most striking features of what the company has to say is the sheer scale on which new submarine cables are being planned. Left to itself—and the FCC is required to license all new developments in international telecommunications—AT&T would like to install cables each with a capacity of 3,500 circuits on several Atlantic and Pacific routes by the mid-seventies. The first of these cables would be laid in the Atlantic in the first half of 1976, and would be followed by a second three years later. A similar stretch of cable would be laid between California and Hawaii in 1977. With the new design would go cheap installation—a mere \$8 a circuit mile for the proposed cable compared with more than \$300 a circuit mile for the first fifty-circuit transatlantic cable commissioned in the early fifties and \$30 a circuit mile for more recently installed cables.

Part of AT&T's case for the continued installation of cable circuits is a wish to avoid having all its eggs in one kind of basket. The documents submitted to the FCC point out that in a year and a half to the end of July, AT&T lost more than 400,000 circuit-hours of satellite time but only 100,000 circuit-hours of cable time. AT&T, the largest carrier of overseas telephone traffic from the United States, is at present using roughly 2,000 external circuits, evenly divided between submarine cable and satellites. The company estimates that it will need 8,000 circuits by 1975 and 20,000 by 1980. Although most of the growth in the cable business lies in the transatlantic area, AT&T has ambitious plans for other routes and is, for example, planning to install a 825 circuit cable westwards from Hawaii in the late seventies.

At this stage, the response of the FCC to this view of how to strike a balance between satellites and cables cannot be predicted. It seems probable, however, that the rash of satellite failures that has recently plagued Comsat, together with the difficulties that persist in the negotiation of a new agreement for Intelsat, will ensure that close attention is paid to what AT&T has had to say.

NEWS AND VIEWS

Molecular Basis of Bacterial Sporulation

THE eighteen months have not been wasted which have slipped by since Burgess, Travers, Bautz and Dunn (*Nature*, **221**, 43; 1969) discovered the sigma factor component of DNA dependent RNA polymerase, the enzyme which transcribes messenger RNA off DNA. The concept of sigma factors has been so quickly assimilated that it is hard to credit that in January 1969 it was a complete novelty making headline news. Today sigma factor proteins, which in bacteria play a part in dictating which genes RNA polymerase can transcribe, are central to all attempts to explain the positive control of gene expression. Admittedly, sigma factors have so far only been detected in bacteria and bacteria infected with bacteriophages, where they transiently complex with the core of the RNA polymerase molecules and ensure that transcription of the bacterial or phage genes is initiated at the correct starting points rather than at random. But, in spite of the pitfalls inherent in extrapolations from bacteria to nucleated cells, it has always been tempting to speculate that sigma factors also occur in eukaryotic cells forming part of the complex switch gear required to regulate gene expression during cellular differentiation.

The experiments of Sonensheim, Losick and Shorenstein, reported on pages 906 and 910, certainly make such speculations more plausible. For they have proved that changes in RNA polymerase play an essential role in an example of bacterial differentiation, the sporulation of vegetative *Bacillus subtilis* cells. Bacterial sporulation involves the metamorphosis of a fragile, vegetative bacterial cell into a dormant, resistant spore and an equally striking change in the cell's biochemistry. When *B. subtilis* sporulates, for example, the pattern of enzyme activities and RNA molecules in the cells changes markedly as the vegetative genes are switched off and the sporulation genes are switched on.

But what effects this change over? Sigma factors soon became strong candidates for the job and subsequent experiments strengthened this suggestion by proving that, during phage infection, phage specified sigma factors displace those of the host and subvert the RNA polymerase to the transcription of the phage genes. A new sigma factor, or some other change in RNA polymerase for that matter, made at the onset of sporulation might switch off the vegetative genes and switch on the sporulation genes.

Last year, Losick and Sonensheim (*Nature*, **224**, 35; 1969) found that early in sporulation the template specificity of RNA polymerase in *B. subtilis* changes. The enzyme loses its capacity to transcribe *in vitro* phage DNA and the phage only grows in vegetative cells. Together with Shorenstein they have now taken their analysis of sporulation one step further (page 910) by showing that the polymerase of the vegetative

cells needs a sigma factor of molecular weight 57,000 to transcribe ϕ e DNA but will transcribe poly dAT without the sigma factor. (Two other groups, Kerjan and Szulmajster (*FEBS Lett.*, **5**, 288; 1969) and Avila *et al.* (*Nature*, **226**, 1244; 1970) have also detected this *B. subtilis* sigma factor.) Moreover, Losick *et al.* find that the RNA polymerase from sporulating cells fails to transcribe ϕ e DNA even when the sigma factor is added. Obviously the core enzyme of the sporulating cells differs in function from that of the vegetative cells, for it fails to respond to the vegetative cell sigma factor.

Losick and his colleagues believe they have found the molecular basis of this difference. One of the two β subunits of the core enzyme from sporulating cells has a molecular weight of about 110,000 while both β subunits in the core of the vegetative enzyme have molecular weights of about 155,000. They envisage that at sporulation part of one of the β chains of the core enzyme is cleaved and the enzyme, as a result, loses both its affinity for the vegetative sigma factor and its capacity to transcribe the vegetative genes which are switched off. Losick *et al.* are currently searching for a new sigma factor, which, they suggest, may appear at sporulation, associate with the modified core and specifically direct it to transcribe sporulation genes. In other words, the transcription switch controlling sporulation may well turn out to be cleavage of part of the RNA polymerase core, displacement of the vegetative sigma factor and the appearance of a new sigma factor switching on the spore genes.

The properties of a class of mutant *B. subtilis* isolated by Sonensheim and Losick (see page 906) strongly support this interpretation. The mutants, selected for resistance to rifampicin, which is known to inhibit directly a step in initiation of RNA synthesis, have also lost the capacity to sporulate. The reversion rates of these mutations indicate that they are single events which affect both resistance to rifampicin and sporulation. Furthermore, the RNA polymerase from the mutants retains its capacity to transcribe ϕ e DNA *in vivo* and *in vitro*, even when the cells are grown in conditions which induce the sporulation of wild type cells. Losick and Sonensheim suggest that these single mutations somehow prevent the cleavage of the β subunit of the core RNA polymerase. The mutant enzyme cannot therefore undergo the modification which results in loss of affinity for the vegetative sigma factor and the switching off of the vegetative genes; cells containing the mutant polymerase cannot therefore sporulate. Recently Doi *et al.* (*Proc. US Nat. Acad. Sci.*, **66**, 404; 1970) have also reported the isolation of rifampicin resistant mutants which produce spores of altered morphology. Their work, like that of Losick *et al.*, points to a change in RNA poly-

merase being a critical factor in normal sporulation.

The implication of all these experiments extends, of course, beyond bacterial genetics. Batteries of different sigma factors may well be involved in the coordinated switching on and off of genes during differentiation of eukaryotic cells; even the transformation of cells by tumour viruses can be interpreted in terms of sigma factors. Polyoma and SV40, for example, replicate in some cells but fail to replicate and trans-

form other cells. Perhaps the permissive cells contain sigma factors which allow the complete expression of the viral genome and the replication of the virus, while the sigma factors in non-permissive cells allow only partial expression of the viral genome. In the non-permissive cells the virus would fail to replicate but the viral genome would be available for insertion into the host cell's chromosomes, an event which may lead to the transformation of the host cell.

Advice for Teminizers

TEMINISM—the activity triggered off by Temin's discovery that RNA tumour viruses can reverse the normal direction of flow of genetic information by acting as templates for the synthesis of DNA—is booming. But a major difficulty in assessing progress, which also seems to be confusing many of the research teams now frenetically searching for information reversal enzymes, is how to decide just which enzyme is fulfilling what function. "Know your enzyme" may be a good motto for Teminizers, but it is proving one difficult to live up to.

The one enzyme whose catalytic function is clear is the so-called RNA dependent DNA polymerase (see *Nature*, **226**, 1209 and 1211; 1970). This acts on the viral genome to synthesize DNA complementary to its RNA. So far, however, the extent of RNA-DNA hybrid formation seems to be rather limited; only a small part of each RNA genome is converted into DNA.

The obvious advantage for RNA tumour viruses to be able to convert RNA to DNA is that their genetic information can then be integrated into the genome of the host cell. This would require the synthesis of duplex DNA from the RNA-DNA hybrid, and at least two further enzyme activities are likely to be involved. (This, however, is not to say that the enzymes are necessarily represented by two distinct protein entities; one difficulty of working with viral information-transfer is that as yet the catalytic activities of the virion have not been identified with protein moieties, and one enzyme may well turn out to have more than one catalytic activity.)

If integration of duplex DNA into the cell genome is to be assured, there must first be a replacement of the RNA strand of the hybrid by a DNA strand, which implies one distinct enzyme activity. This single piece of duplex DNA will then probably need replicating so as to provide more copies, which is another enzyme activity. Distinguishing these two enzyme activities *in vitro* is difficult enough, but finding out just how they work *in vivo* may prove impossible until the protein(s) responsible can be characterized. And even these are unlikely to be the only enzyme activities involved. It is possible, for example, that more viral RNA may be synthesized from the DNA-RNA hybrid, and integration of the DNA itself will probably demand yet more enzymes, such as a nuclease to prepare gaps in the cell chromosome at the sites where duplex DNA

is to be inserted. Indeed, the identification of the enzymes involved in this process may well throw light on the vexed issue of recombination, a closely analogous process, the details of which remain largely elusive in more conventional systems.

CANCER VIRUSES

More of the Same

from a Special Correspondent

If people were obliged to publish anonymously, tragicomic situations such as that revealed last week at the 1970 Tumor Virus Meeting at Cold Spring Harbor might be less frequent. If a prize were to be given for the work that has caused the most whip-cracking and unnecessary duplication of experiments, Temin, Mizutani and Baltimore would win hands down. Even the most innocent enthusiasts must now be having second thoughts, however, when so many groups are busily copying each other, characterizing RNA dependent DNA polymerase and the other enzymes in RNA tumour viruses. To judge from the remarks of Dr T. E. O'Connor (National Cancer Institute), however, those who run the institute's Special Virus Cancer Program are all too keen to pour even more money into an instantaneously overcrowded field. He invited the packed hall—the idea that the specialist meeting at Cold Spring Harbor should be intimate and eclectic has gone by the board—to send requests for free samples of RNA tumour viruses to Bethesda as soon as possible. The programme, which must be delighted at the prospect of finding something on which to spend its millions, would then be able to match supply with demand. Feline leukaemia virus is included in the offer, albeit with a mild caution that a virus that jumps species barriers so readily and which grows well in human cells might be dangerous. It is therefore hardly surprising that the standing sick joke has become that, because it is proving hard to find even epidemiological evidence of human RNA cancer viruses, the Special Virus Cancer Program will be content if its pensioners manage to manufacture them in their laboratory.

And what are the fruits of two months' frantic activity? Mizutani and Temin (Wisconsin) have now found two more enzymes in the virions of mouse sarcoma virus—an endonuclease activity which one can speculate may have a role in integrating the viral DNA into the host cell chromosomes on transformation,

and a DNA dependent DNA polymerase which connects the RNA/DNA hybrid made by the RNA-dependent DNA polymerase into double-stranded DNA. Both Spiegelman (Columbia) with his six colleagues and Green (St Louis) with his five colleagues reported that they, too, had detected the enzymes which made double-stranded DNA. Spiegelman also finds that a synthetic polydeoxy-C-polyribo-G is by order of magnitude a better template for the DNA dependent DNA polymerase than anything in the virion. Spiegelman also finds that a polydio-C-polyribo-G is by order of magnitude a better template for DNA-dependent DNA polymerase than anything found in the virion and both Green and Levinson (San Francisco) reported that there are probably small amounts of DNA within the virions of some RNA tumour viruses.

The DNA tumour virologists, who by now must be seriously questioning whether work in DNA tumour viruses will continue to be funded although the discovery of the reverse transcriptase makes the distinction between DNA and RNA tumour viruses little more than academic, held the stage but not the limelight for the first two-thirds of the meeting. Isolation of temperature sensitive mutants of SV40 was reported by Robb and Martin (NIH) and Kit *et al.* (Baylor, Houston) and Eckhart (Salk Institute) described the four classes of polyoma mutants he has isolated, while Hirt and Gesteland (Cold Spring Harbor) and Estes *et al.* (North Carolina) proved that the proteins of SV40 virions closely resemble those of polyoma virions.

PROTEINS

Membranes Dismembered

from our Microbiology Correspondent

By one of those mysterious mass movements, like the swarming of bees or the migration of lemmings, protein chemists seem with one accord to have surged into the membrane field. One's sympathies are with the aboriginal inhabitants, who, after ploughing their lonely and leisurely furrow these many years, have now been overwhelmed by a plague of voracious locusts. Of course there is at this stage no lack of sustenance, for the subject is in a highly interesting state. The newer methods of protein chemistry are starting to pay off, and the systematic attempts now in progress to extract and characterize the proteins of membranes are beginning to impose some sort of pattern.

The attempt to dredge individual components out of the porridge has been motivated either by the desire to localize and isolate a particular biological activity, or by the hope of discovering some features of general structural importance. Both these lines are generously represented in the current literature. One observation of great interest on the proteins of a bacterial membrane has been recorded by Patterson and Lennarz (*Biochem. Biophys. Res. Commun.*, **40**, 408; 1970). Working with an organism presumed to derive from a strain of *B. megatherium*, and dispersing the total protein of the ghosts by treatment with deoxycholate and urea, they fractionate the extract by acrylamide gel electrophoresis and find that no less than 90 per cent of the total protein mass is contained in one component. There is also a series of minor components.

As judged by the detergent-acrylamide gel method, the molecular weight is some 30,000. Examination of the putative parent, *B. megatherium*, strain reveals the usual spread of constituents, one of which corresponds, at least electrophoretically, to the mutant component. On this evidence then, it seems that viable membranes can be assembled from only one major structural protein—a thought-provoking observation.

Phillips and Morrison (*ibid.*, 254), working with red cells, report that when the intact cell is exposed to iodination in conditions involving catalysis by a peroxidase enzyme, only one protein incorporates iodine. It has a molecular weight of about 90,000, and they favour the conclusion that it is the only protein on the outside surface of the cell. It is also possible of course that there are other proteins devoid of accessible tyrosine residues. This sort of experiment will undoubtedly gain currency, however, for exploring the distribution of components in the membrane.

Gwynne and Tanford (*J. Biol. Chem.*, **245**, 3269; 1970) have dispersed red cell stromata with concentrated guanidine hydrochloride, together with reducing and alkylating agents, to eliminate disulphide links. All the proteins were solubilized by this means, and the mixture was then applied to a column of 'Sepharose'. As Tanford and his associates showed earlier, the elution volume of such fully disordered polypeptide chains is a measure of their molecular weight, all the evidence being that only single, unassociated chains can persist in the solvent. At the head of the fractions eluted from the column, Gwynne and Tanford found a giant chain of molecular weight 200,000. This value was confirmed by sedimentation equilibrium. This is in any circumstances a protein of unusual size, and contrasts strangely with the mass of rather low molecular weight proteins previously found to make up the bulk of the red cell membrane.

A more genteel approach to the study of membrane proteins is to try to label and identify active components. Thus Panet and Seliger (*Europ. J. Biochem.*, **14**, 440; 1970) have taken advantage of the stability of the ATPase of sarcoplasmic reticulum, when it is protected by its substrate. In the absence of ATP, treatment of the membrane with thiol reagents leads to the uptake of fourteen labelled reagent molecules per 10^5 g of membrane when detergent is present, or ten when it is not. In either case the ATPase is inactivated. When ATP is present, one of the ten reactive thiols, and also the enzymatic activity, are protected. If all available cysteines are then blocked with an unlabelled alkylating reagent, and after removal of ATP a radioactive alkylating agent is introduced, only the ATPase should take up the label. It turns out indeed that only one radioactive zone appears in gel electrophoresis, compared with eleven alkylated proteins in all, so that the ATPase is unambiguously identified. The same general strategy for isolation of a protein of known function, using instead a labelled specific active site reagent, allowed Bellhorn, Blumenfeld and Gallop (*Biochem. Biophys. Res. Commun.*, **39**, 267; 1970) to purify an acetylcholinesterase from human red cells. Dunham and Hoffman (*Proc. US Nat. Acad. Sci.*, **66**, 936; 1970) have used tritiated ouabain, which is an active-transport inhibitor, to identify its target in the membrane. After solubilizing the total protein, the label is found in a rapidly sedimenting fraction, which coincides, as it should, with the sodium-potassium ATPase activity.

NUCLEIC ACIDS

Rules for Sequencing DNA

from a Correspondent

THE seemingly insurmountable problems involved in sequencing DNA molecules, or even substantial pieces of them, have always provoked stock responses about the necessity of finding specific deoxyribonucleases. This, however, is probably less important than choosing a promising DNA of modest size to work on (such as the reiterated sequences in some mammalian satellite DNAs being studied by Southern and Walker), and using adequate methods for fractionating fragments of it. Some of the technical foundations for the latter task have been laid down recently by K. Murray (*Biochem. J.*, **118**, 831; 1970) in a vast and painstaking study of oligodeoxynucleotide mapping procedures, lasting several years. He started with the methods devised by Sanger and his colleagues which have proved so successful in the sequence analysis of RNAs.

Murray used ^{32}P -labelled DNA prepared from *Escherichia coli* and the bacteriophages λ and fd as substrates. First, he fingerprinted digests of *E. coli* DNA carried out with pancreatic deoxyribonuclease and a deoxyribonuclease from the mould *Neurospora crassa*.

He used the standard method of electrophoresis on a strip of cellulose acetate at pH 3.5, followed by electrophoresis on DEAE-paper at pH 1.9. The fingerprints were qualitatively similar, and reproducible in defined conditions of digestion. Murray then analysed, fully or in part, about seventy spots ranging up to tetranucleotides in size. On the basis of his results, devotees can easily see that the oligodeoxyribonucleotides are fractionated in a similar way to oligoribonucleotides, falling into "graticules" according to their compositions, but the picture is complicated because of the lack of enzyme specificity, so that all the isomers of the smaller sequences arise as products of digestion. Many of these were separated from each other during subsequent fingerprinting, but the very complex mixtures of larger oligonucleotides were not fractionated by this system, and so Murray modified the fingerprinting procedure in two ways. This greatly improved the resolution of these larger products. In one case he carried out the first dimension of electrophoresis at pH 9.7 (5 per cent triethylamine carbonate) on DEAE-paper.

He also used a system in which DEAE-paper was replaced by AE-paper in the second dimension. He indefatigably constructed further maps, after examining about 120 products fractionated on the system using triethylamine carbonate, and another 110 products on fingerprints prepared on AE-paper.

There was, however, a rather unfortunate denouement when Murray attempted to compare the DNAs from *E. coli* and phages λ and fd. Pancreatic deoxyribonuclease fingerprints of these molecules gave essentially similar pictures, and it was not possible to ascribe any definite significance to the slight differences observed. The lesson must surely be that even these comparatively small DNAs are far too complex to be readily amenable to these methods. It will probably be several years before a roll of DEAE-paper and a strong constitution are all that is required to sequence λ DNA.

EARTHQUAKES

Why Chandler Wobble?

from our Geomagnetism Correspondent

ALTHOUGH the Chandler wobble, the precession of the Earth's axis of figure about the axis of rotation, was discovered in 1891, its cause is still a mystery. There are, in fact, two separate puzzles involved—the source of the excitations which produce the wobble of amplitude about 0.5", and the width of the spectral peak which indicates that the period of fourteen months varies within ± 4 per cent. The simplest explanation for the varying period is that it results from continuous excitation of a mechanical system whose natural period changes with time; but it is unlikely that physical changes in the Earth would produce the observed variations over times as short as a year. Alternatively, the Earth could have a fixed Chandler period produced by random excitations which are subject to damping. This is much more reasonable, especially as theoretical calculations of the period turn out to be about 1.20 years.

But what energy source maintains the random oscillations? During recent years it has become popular to imagine that this source is earthquakes; and this view has received considerable support from theoretical calculations which show that, given the right conditions, one large earthquake could produce 10 per cent or more of the observed Chandler wobble amplitude. If a single earthquake can do this, it seems intuitively likely that all earthquakes together could account for the whole of the Chandler wobble. Ben-Menahem and Israel (*Geophys. J.*, **19**, 367; 1970), however, are more pessimistic. They show that a single shallow earthquake of magnitude 8.5, occurring at a suitable latitude and with a favourable strike-azimuth, could maintain the Chandler wobble for about a year—and yet they conclude, paradoxically, that the total number of real earthquakes could account for only about 30 per cent of the observed wobble amplitude and corresponding secular polar shift.

The reason is, of course, that the secular polar shift produced by an earthquake is critically dependent not only on the shock's magnitude but on its position and its strike and source parameters. An earthquake of magnitude 8.5 may maintain the Chandler wobble for a year under optimum conditions; but an earthquake of that magnitude only occurs about once every 4 years, and when it does the conditions for Chandler excitation are far from optimum. If all the annual seismic energy were to be released in a single shallow strike-slip rupture on a meridional fault located at the equator, then again the resulting annual shock would be sufficient to drive the Chandler wobble for ever. In practice, circumstances are far less favourable.

It is important to realize, however, that Ben-Menahem and Israel have derived their conclusions from a mathematical model. It turns out to be a model which is considerably more favourable to the excitation of Chandler wobble by earthquakes than models previously used to describe the same effect—but it is a model none the less, and is therefore subject to simplifying assumptions. Thus Ben-Menahem and Israel have not proved conclusively that earthquakes do not account for Chandler wobble because some assumptions may not be valid and modifying conditions may remain to be discovered. For this reason, we have certainly not heard the last of earthquakes as the source of Chandler wobble.

New Knowledge for Old

by

J. M. ZIMAN

H. H. Wills Physics Laboratory,
University of Bristol

This article is a shortened version of the fourth annual Aslib lecture, which Professor Ziman delivered on April 22 under the title "The Light of Knowledge: New Lamps for Old".

At last year's meeting of the British Association¹, I tried to give an account of the communication system of science, and to explain its rationale as a social organization. So much has been preached and prophesied against our conventional system that it seemed useful to make explicit the function that it is designed to serve and the reasons for some of its peculiar features, before we decide to take it all to pieces and build a far far better world.

This time, I want to ask a different question: what sort of communication system will the scientist of the future devise, instinctively, to suit his needs? Since we know nothing for sure about this hypothetical person, this article is pure speculation; but science fiction may be as effective as history in the spinning of fables and the manufacture of myths.

The Conventional System

First I shall draw attention to three characteristics of the orthodox system of scientific communication, as we may find it in learned journals, treatises, and handbooks. The primary function of an ordinary scientific paper is to bring into the public domain an explicit account of some new scientific development or discovery. As I have argued at length², the whole activity of science is dependent on the publication of such documents, and their subsequent criticism, re-evaluation, and eventual acceptance or rejection as parts of the consensus of "Public Knowledge".

But scientific publication is also essential in the social system of science as the registration of priority of discovery. In other words, since research is the production of new, useful, "consensible" knowledge, the original papers of a research worker are the tangible evidence of his ability to do research.

Finally, I would draw attention to a uniform characteristic of the whole conventional system: the user of the information pays all the costs of publication. Books and journals are published by learned societies and commercial organizations, and sold for profit—or at least to cover all the printing costs—to individual research workers or to the organizations for which they work. The library is a cooperative of readers, not authors. This is a point of some principle, for it is the ultimate source of the power of the scientific editor or referee or librarian; he may reject a work on the grounds that it will lower the standard of his journal, or monograph series, and hence endanger its financial viability.

Crisis of Over-population

This conventional system is now in a state of crisis, due chiefly to the enormous expansion of scientific activity in the past few decades.

I shall look at this crisis from three aspects. Much discussion has concentrated on the difficulties of indexing, abstracting, and assimilating the vast quantity of new

material, proliferating from many breeding grounds and overrunning the poor scientist who is just trying to keep up with the literature. This seems to me to be largely a technical problem that can be solved quite effectively if we are prepared to put sufficient resources into it. But a "technological fix" with arrays of half-witted computers is not the only answer: there is still plenty of scope for development in the old fashioned procedures of compiling, indexing and printing up-to-date collections of abstracts and reviews.

A more intractable consequence of the expansion of science is the debasement of the criteria of publication. Not only is there too much scientific work being published; there is much too much of it. The need to get recognition by publication forces each of us to shout a little longer and louder so as to be noticed at all in the swelling crowd of voices. If we cannot get into the quality journals, we send our pitiful contributions to a second rate publication, produced perhaps by a commercial publisher who has learned that vanity will get him a distinguished-looking list of editors and the professional zeal of librarians will ensure that he gets his money back. Or we may simply have our work printed, or duplicated, as a "technical report" or (hopefully) as a "preprint", and send it round free to everybody whom we think ought to be interested. However hard we try as editors to keep up standards, the referee system is being eroded at the edges.

Another serious consequence of the expansion of science is a steep rise in the cost of information services. If we conceive of an information system as a network of pathways from individual to individual, then N individuals generate $\frac{1}{2}N(N-1)$ separate channels of communication. Thus, as N increases, the number of channels required by each individual also increases. If the bulk of literature in his subject is growing, then it costs him more to purchase all the journals and books he needs, whether from his private purse or through an institutional library. For the individual scientist these costs can be kept down by only purchasing material within his own specific field. But for institutions such as universities, this economy is not available, and scientific library costs are really beginning to hurt. In rich countries, this extra burden can be carried; but for many developing countries, and especially those states with pathological objections to the expenditure of foreign exchange, scientific progress is now hobbled almost to a standstill by the inability to buy the full range of publications that now contain the modern stock of scientific knowledge. The attempt to solve the information crisis by computerized retrieval aggravates the position of a university or research institute in India, Africa, or Latin America, for whom these gadgets are much too expensive. I do not know whether anyone has calculated the cost of such devices per research worker using them, but it would be tragic if they came to seem indispensable.

Industrialization of Science

It is my impression, however, that discussion of the information crisis has seldom been accompanied by a recognition of the rapid structural changes that are taking place within the scientific community which the communication network is supposed to serve. The tacit assumption of the librarian, journal editor, information officer or scientific publisher is that he will always be dealing with the products and needs of individuals.

It is obvious, however, that scientific research is rapidly evolving from a cottage industry to a system of factory production. This, surely, is an inevitable consequence (if not, also, a cause) of the recent enormous expansion of science. Is this not the appropriate simile for those vast hives of scientific buzzing and honeymaking that we now observe throughout the world, those national laboratories, research institutions, institutes for atomic energy, or for cancer research, or for apple growing, or for seaweed, or for noise, or for space, or for higher thoughts, or for lower temperatures, or for advanced studies, or for retarded minds? Faraday and Edison, Pasteur and Darwin—they were individual artists or artisans, with perhaps a few apprentices as extra hands; their successors are executives, captains of industry, directors of research, managers of departments, chairmen of research councils, and other high-powered bureaucrats.

To some extent this development flows from the demands of "big science"—especially in applied research and development. There are economies of scale and natural psychological tendencies; not to mention factors of efficiency and tidiness in the minds of the administrators of government grants. Whatever the reasons, good or bad, the fact of industrialization and bureaucratization of science remains.

The consequences of this historical development for the life of the mind have not been discussed seriously; perhaps we cannot discern the effects ourselves, as the wave breaks over our heads. But I would draw attention to two obvious changes in the personal status of the scientist: he becomes more professional, and more subordinate to a team activity.

Until quite recently, the bulk of scientific research was done by university teachers, not as an explicit part of their employment but as a semi-independent, personally directed activity, motivated by the desire for further preferment as a reward for scholarly prowess. This pressure could be agonizing⁴—witness the bitter struggles of Sigmund Freud to achieve recognition for his discoveries—but it was indirect and unspecific. The official doctrine was that a university lecturer, being called to the vocation of high scholarship, would naturally wish to add to the corpus of pure learning, and was given the freedom to make the best of his time in that way. Within the bureaucratic institutions of our day, this amateur status has been renounced. Whatever freedom he may have in the day-to-day, month-to-month, even year-to-year direction of his research, the modern scientist is none the less paid to be a research worker, and is expected to produce some results of a publishable or useful kind, in return for his stipend.

In the best research institutions, an effort is made to preserve the freedom of the individual scientist in his choice of problem and in the tactics of his research. Nevertheless, the tendency towards team work grows ever stronger. In big science⁵, the experiment, and the discovery that arises from it, is not a product of the ingenuity of a single mind, but of a large group, with members who specialize on different aspects. The evidence for this

multiple effort is the multiple authorship of the paper in which the results are reported—a dozen, a score, even half a hundred names appended to the publication. The individual skills required may be of the highest order, but the "productivity" or "creativity" of each participant is merged into the collective mind of the team. An investigation that costs a million dollars is clearly a large scale social activity, not at all the same thing as a personal work of art for which credit may be assigned to the individual creator. The very idea of tussling with a problem of natural philosophy may be forgotten in the struggle to achieve some immediate technical aim within the vast framework of the apparatus.

Effects of Industrialization

What will be the effect of this change in the social and psychological structure of science on the information system? First, it is obvious that there is a grave threat to the convention of awarding promotion, or other forms of recognition, on the strength of published work. The mere fact that a candidate for a lectureship in elementary particle physics has his name among the dozens of "authors" of some significant discovery says little about his scientific skill. In the long run, the leader of such a team gets the credit for its contributions to knowledge, but he must be already the selected and tested boss of a big group. Evidence of ability at a more junior level can only be assessed within the framework of the project itself, just as it would be in an army, a civil service or other bureaucracy. With direct power in the hands of the seniors, one of the primary functions of the conventional communication system of science is losing weight. The necessity of maintaining an open market for the creations of the individual scholar, as objective evidence of achievement and promise, is no longer evident.

On the other hand, the funding of research on a vast scale, the assumption that every scientist is a professional, employed and supported materially by a large scale institution, makes it easier to find the money for expensive new techniques of communication. We begin to take it for granted, for example, that we may charge to laboratory overheads our long-distance telephone calls, which we would never dream of paying ourselves. Air mail for reprints, air travel for conference participants, secretarial assistance, Xerox machines, electric typewriters, photo-offset printing, all are enlisted in the battle for more and more rapid, total, instant, informal communication. It is easy to prove that such aids, although not of negligible absolute cost, pay for themselves many times over within the context of million dollar research budgets, palatial buildings, gargantuan machinery and armies of assistants.

The question that has not been resolved is how this money is best spent in the support of the formal communication system. In practice there are two divergent trends. On the one hand, the provision of more and more lavish library facilities is taken for granted, along with the new gadgets for information retrieval and search. As I have remarked, the affluence of science in the more industrialized nations can easily keep pace with the flood of new publications. The assumption is made that library funds will always be increased to permit the purchase of all the new periodicals and books that are relevant to the research in hand, with lavish allowances for treasures that may still be unearthed in the older literature. The recognition that these costs are really trivial by comparison with overall expenditure on buildings, equipment, technical staff and professional salaries was the secret of

at least one great fortune in the technical publishing world—and it remains largely true today. Some scientists have jibbed at the enormous expense of such marginal aids as the *Science Citation Index*, and are worried at the high prices now being charged for advanced treatises and other books, but they can still maintain an open-ended commitment to obtain all the genuine literature of science without making deep inroads into overall research budgets. Thus, the financial power of bureaucratic science is put at the disposal of the users of information; the larger the scale of the laboratory, the easier it is to provide such facilities on a collective basis.

On the other hand, this financial power is being applied to the information system at the producer end. I have already referred to the growth of the "Report" literature, especially within the very large government agencies and industrial laboratories. This material may not be produced in the full glory of letterpress, but the re-typing and duplicating of a few hundred copies of a 20 page report or preprint, not to mention air-mail postage and incidental overheads, is not a negligible expense. The fact that it is distributed free—that it is almost forced upon one, like an advertisement for laboratory equipment or life insurance—is in striking contrast to the high subscription one has to pay to read the same article, only a few months later, in a regular journal. The pressure to get into print, for professional prestige and preferment, is thus diverting a substantial amount of research funds into the information system, but in an extravagant manner that is largely dysfunctional to the scientific community, through the degradation of standards and the clogging of the channels by multiple publication of the same basic research.

A parallel development is the rapid growth of the page-charge system. The ancient custom of supplying offprints is not begrudged as a service to friends and colleagues who might find it convenient to have a good printed version of the article ready to hand. But this has now been inflated into a really steep charge—\$80 per page in the *Physical Review*—levied on the institution of the author when the paper is accepted for publication. It is argued that publication is part of the overall research activity, and therefore its cost should be met out of the research grant, or other fund, that pays the salaries and equipment of the researchers.

This is perfectly logical: but it does conflict with the general principle that publication of scientific information is paid for—hence, eventually controlled in quality—by the reader. The actual pressure behind page charges is the desire of each editor to keep the selling price of his journal within the means of the individual subscriber. This is particularly so for the great scientific societies, whose members have become accustomed to receiving their journals at quite a modest price, as a special concession and a service. I belong to the American Physical Society, not out of international brotherhood and solidarity, but because I can get a great deal of valuable scientific material—several thousand pages a year—for a subscription of only \$50 or so. It is a good bargain, and would be particularly significant if I were working in a developing country where library costs were a real burden.

Nevertheless, page charges become a tax on research, and can only be borne by heavily bureaucratized science, where the employee can assume that somebody else is picking up all the checks. The small research group, still trying to produce in the cottage industry mode, gets squeezed out. Is it really the intention of the American

Institute of Physics to prohibit in its journals any publications from the outside, dollar-less world? I certainly do not propose to spend the salary of a good research assistant on having the papers from my own research group published in the *Physical Review*, when I get them printed for free in the corresponding British journal. The AIP says, of course, that the charge is not obligatory: but it is now delaying publication of papers from "irresponsible" institutions that do not "honour" their page charges, and has begun to ask higher subscriptions from foreign members on the grounds that we are not paying our fair share of the printing costs. In other words, we are approaching a situation in which the whole scientific community of the United States is regarded as a single body, supported financially and thereby controlled by the major funding agencies of the government. This support is not a disinterested gift to learning and to humanity, but it is evidently calculated as the cost of buying certain specific services for the nation.

I do not propose to discover conspiracies, nor to denounce the more sinister aspects of the world we live in: in any case, the brutal bureaucratization of science in the Soviet Union and its colonies is far more tragic and foolish than any situation they can manage to bungle their way into, through sheer expediency, in the United States. The significance for the information system is that the institutions that employ the scientists and treat them as a category of skilled manpower are now laying their hands on the information system, and beginning to take charge of the mechanisms for the publication of knowledge.

We are now in a state of transition. The individual scientist—or at least the leader of the research group—is allowed to say what he likes, how he likes, and takes personal responsibility for his research results just as if he were an old-fashioned professor. He may, indeed, have at his disposal the funds to advertise his work through the distribution of reports and preprints, without any critical check. On the other hand, he must still submit his results to the scrutiny of independent anonymous referees if he wishes to see them published in a respectable journal. The financial power of the laboratory that employs him is not used to interfere significantly in the form and substance of his published work.

How long can this situation continue? Will there be, before long, a tightening of the strings within the bureaucratic organization, so that the decision to support publication will rest with higher authorities than the man who really did the research? In a new historical phase where money has suddenly become tighter for research, it seems inevitable that more careful control of page-charge, report, and reprint costs will be exercised, so that only work judged worthy by the senior officers within the institution will be cleared for publication. To anyone familiar with scientific controversy, and the self-righteous malice of the second rate senior scholar found in the wrong, this is an unhappy prospect. The history of Lysenkoism⁶ shows the destructive effect of ignorance and incompetence when it gets its hands on the levers of power of a complete bureaucracy, and controls publications as well as employment. We could see a covert conspiracy of the publishing monopolies with the scientific institutions, in which awkwardly critical or uncomfortably heterodox research could get no public hearing.

I am not quite so pessimistic as this. I suspect that the institutions will take firmer control of the publications of their employees, and insist on higher standards of style and achievement before they will pay the bills. In

other words, the published work emanating from a particular laboratory may be seen more and more as a product of that laboratory, rather than as the creation of an individual scientist who only works there (witness, for example, a paper by "Orsay Liquid Crystal Group" in ref. 7). As it becomes more difficult to make a name for oneself by one's personal list of publications, the pressure to put on the market vast quantities of half-baked material may recede, and a longer rhythm of work, with less frequent, less fragmentary papers, may succeed. Of course, there will still be tremendous competition for priority of discovery between groups in different laboratories, but this may well be catered for through the informal system of letters, preprints, and so on. The actual number of papers ceases to be of much significance as a standard of productivity by a substantial institution.

We could arrive at a situation where in practice the role of the referee, as a professional critic, would be performed mainly within the producing laboratories, or even within the research team itself. It must be remembered that the function of the editor of a journal, or of his anonymous referees, is not to guarantee the complete scientific validity of every paper that eventually gets published. One only finds this notion in the minds of certain notoriously hypercritical scholars, who eventually get dropped from the panel of experts! The job of the referee is to confirm that the work is scientifically interesting, more or less original, reasonably well expressed, and not vitiated by obvious errors that the author can be persuaded to acknowledge. It provides a barrier against irrelevance, crankiness and gross incompetence—not against mild stupidity or subtle mistakes. These conditions can be met quite easily by the informed critical examination of work in progress within a capable team or well-established laboratory. In other words, I am prepared to believe that the standard of work published at the behest, and in the name, of a well-established laboratory or other scientific organization might be somewhat higher than the average produced by individuals in the current literature.

Shall we then see a new system, in which the great scientific corporations announce their discoveries in "house journals", edited internally and distributed free? In general, such a system would not conflict with the fundamental characterization of science as a community devoted to the creation of "consensible" knowledge. Given reasonable freedom of speech and action within the corporate institutions, critical comment and the eventual arrival at a rational consensus would still be achieved. The "scientific attitude" has become so engrained in the thinking of a generation of professional research workers that even such power structures as Lysenkoism can be defeated by an appeal to simple fact and straight logic⁶.

But it seems essential for the preservation of this attitude that the bureaucratic corporations should not monopolize the sources of information and means of communication. One single international institute of high energy physics, dominated by its trillion volt machine and controlling all the media of publication in this field, would be a monstrosity. Competition for priority between individuals must be transformed into intellectual controversy between co-equal groups and teams, with public debate and open criticism the major weapons.

It is particularly important that the old style journals, published at the expense of their readers and preserving high standards through the use of anonymous referees, should not fall for the expedient device of the page charge.

As I have said, there is a danger that the learned societies may fall in with the bureaucratic trend, and fail to protect the rights of those of their members who still have freedom to do research on their own account. Can't you just see it? A paper arrives from a private address. "Don't know this name. . . . Doesn't seem to be in the directory of PhDs. . . . Where does he work? Seems to be doing some desk job in the Patent Office. . . . They don't have a programme in astronomy, surely. Has he got permission to publish from his research manager? I bet they won't pay their thousand quid for this stuff. I'll call up the Director: what was the initial; oh yes: A for Albert—OK, I've got it. Albert Einstein."

To maintain the older system of scientific communication within the framework of the new bureaucracy and the new technology will not be cheap; to many, it may seem no more than the preservation of a charming traditional custom. The new procedures which I have sketched out will have many advantages, permitting extensive rationalization of the information network, and much easier access to libraries, computerized indexes and other means of information retrieval. Whatever is published by the great laboratories and other corporate bodies may be better written, better printed, more uniformly of scientific interest, and better indexed than anything in the past. For normal science—the solving of puzzles within an accepted framework of ideas, by well organized teams, using expensive apparatus, under the direction of experienced professionals—this may be the best way to do it. But the mechanisms for revolutionary transformations of thought such as those generated by a Darwin, a Mendel, a Wegener, a Planck, have always been frail, and must be preserved at all costs. I am sorry for the Indonesians and Bolivians, unable to buy all the journals they need to keep themselves scientifically informed, but I do not think it would be to their benefit if the world's scientific literature were given away, like advertisements for patent medicines, yet all doors were then closed to the publication of their own modest researches.

Books and Bureaucrats

I have left to the last the very important problem of reviews and books within the framework of big, corporate science. As I have already suggested, the supposed crisis in technical book publishing, with hard cover or even paperback editions pricing themselves out of the market⁸, is not the real issue: the difficulty is to get them written in the first place. There is already a serious lack of incentive towards review writing, instead of primary research¹, fostered by a false philosophy of originality and "creativity". It is held to be a waste of talents (however modest!) to "take time off from research" for the supposed drudgery of this "derivative activity". Even within the conventional system, the writing of books and review articles has become intellectually devalued, and is no longer regarded as a high art of scholarship, contributing greatly to the furtherance of knowledge and winning laurels of fame for the author.

Of course, the financial rewards are usually modest. If scientific books were composed by professional writers, then we should have a depressed class of hacks on our hands, as poor as would-be novelists and infinitely duller. In practice most reviews and books are written by people already enjoying a full academic or other institutional income.

The bureaucratization of science weights the balance even more heavily against the writing of reviews and

books. It is psychologically much more difficult for the member of a team to withdraw himself from active experimentation than it has been, in the past, for the lone individual. Imagine yourself, once more, in a group devoted to high energy physics or to space research. The experiment has been planned several years previously, as part of a complex continuing programme. The technique of observation, the design of the apparatus, the testing, proving, and running of the equipment, are all novel, and only marginally reliable. The whole process, spread over many months, is a race against time. There are continual crises, and conferences, and unplanned modifications to develop and test: and skilled manpower is in short supply. How can one possibly withdraw from such activity with its clear and immediate goals just to sit, and think, and write a few hundred words, and scratch it out again, and wander aimlessly round the library seeking inspiration, and go back to the desk, and try again to express with due clarity and simplicity the convoluted thought one has nearly mastered in another man's work. In the busy workaday world of making, mending and doing, this looks like *dolce far niente*, or even treason: "We've no room for passengers on this craft," says the leader of the team—handing one a monkey wrench, and indicating the vacant place around the apparatus where it is to be applied. If one is trained from manhood to work in such a team, one can scarcely abandon one's friends and colleagues in such circumstances.

Even the individual, lone scientist, employed by a university or other institution, may come to feel that he is not really earning his salary if he spends his working time in this apparently unproductive activity. As can readily be shown, by an appeal to the general principle that science is public knowledge, necessarily subject to a continuing process of critical assessment and re-integration, the activity of the review writer is quite as important to the scientific community as the making of "original" discoveries—but the purpose of the bureaucratic research corporation does not extend that far. We face, indeed, one of the familiar paradoxes of society—the "crisis of the commons"⁸—in which the immediate self-interest of the individual is best served by his adding another goat to the grazing herd, rather than by fencing and controlling the use of the common land. In so far as the individual becomes the paid employee of the purely selfish and soulless corporation, he loses his liberty to act in an enlightened way in recognition of the needs of the community. In other words, the shallow philosophy of "getting on with one's work"—that is, piling up research findings—is actively reinforced by the attitudes of management, dominated by quantitative measures of "productivity" and "creativity" and not caring at all about the general health of the art.

Review and book writing is thus driven into the "spare time" of the scholar—evenings, week-ends, and occasional sabbatical leaves. Even in the university it is not considered proper for any scientist except a professional "theoretician" to spend his ordinary working hours in this way. There could develop a threat to the modest financial rewards to be won by this extra effort—high taxation on additional earnings, or the demand that "outside" income by holders of academic posts be disclosed and curtailed in the name of equality, fair shares, and maximum productivity.

We must evidently begin a campaign now, before some sort of disaster of fragmentation falls upon the whole system of communication in science. A number of lines

of action suggest themselves. The providers of research grants, for example, might consider much more seriously the explicit subsidization of such writing, by providing funds for sabbatical leave that would free a university teacher from his everyday duties for a certain time, not to do more experiments but specifically to write. There have been occasions when the writing of a book has been proposed as the goal of a research project, but from what one hears this is not usually received with favour by the expert advisory committees, who perhaps set much higher standards for what they regard as the essentially mechanical work of surveying what is already known than they do in estimating the likelihood of success of a proposed new investigation. They must be made aware of their own unconscious belief that writing is really much more difficult and dangerous than experimentation (for it exposes the mind and soul to criticism and ridicule) and therefore be lenient and generous towards those who are willing to give it a try.

Within "big science", it may be necessary to assign the role of "scribe" or "theorist at large" to a particular member of the team, or to provide income and facilities for a number of such experts within the institutional framework. Perhaps this is already happening—for example in the enormous space-science corporations and administrations. But notice the danger of specializing and professionalizing this particular role. The knowledge and learning to write a review or book come only by direct experience at the research front, by participation in the uncertainty of experiment and argumentation: no amount of external reading around a subject can give one the feel of it. Thus, every research scientist ought, from time to time, to put on for himself the mask of the reviewer, to see his subject whole and express his own wisdom; he cannot leave this essential task to a hired writer, however expert at grammar and syntax. The invitation to assume this persona could as properly come from his research manager or other bureaucratic superior as any instructions concerning research to be undertaken or classes to be taught.

Finally, the new tendency for the cost of the information system to be met by the producer rather than the reader might be allowed to take effect here too. The books written by those employed for that purpose by corporate bodies could be produced cheaply, and heavily subsidized, in the name of scientific progress. If the incentive of royalties and other personal rewards is still to be active, then a substantial subsidy to non-profit publishers might make it much more worthwhile for authors to stop research or teaching for a while. The book-writing world, fiction and non-fiction, has such a peculiar economic structure, and seems to defy so many of the theorems of the market place and factory, that one cannot predict just where and how the extra funds would have the best leverage—but it seems to me essential that corporate action be taken to restore to the scientific community as a whole these services that are now threatened.

Unification of Foetal and Neonatal Immunology

by

J. B. SOLOMON

Department of Bacteriology,
University of Aberdeen,
Scotland

By applying age equivalence to available information it is possible to show that the onset of immunocompetence occurs at the same stage of physiological development in all mammals and birds.

RAPIDLY increasing knowledge of immunological function in the fetuses of many animals emphasizes the need for some means of comparison between the species. Animals pass through similar morphological and physiological phases during foetal development, yet some species seem to become immunocompetent long before others. If some method of direct comparison of physiological age could be devised, we might pinpoint the significant stages in the immunological development of all animals. In this article I assemble and compare the present somewhat fragmentary knowledge of the onset of immunocompetence among various species by age equivalence, and confirm that animals become immunocompetent at a similar stage of physiological development.

Sirotonin¹ and Zdrodowski² have proposed that the immunological maturity of a newborn animal could be related to its physiological maturity. The chief difficulty is to define "physiological maturity"—a question I have discussed at length³. Witschi⁴ made a pertinent contribution in emphasizing that birth occurs at different ages not only in chronological time but in terms of the degree of physiological development. Clearly, a hamster, born after only 16 days of gestation, is much less mature than a newborn guinea-pig which has been *in utero* for no less than 62–65 days. The student of foetal immunology would like to know if a newborn guinea-pig is immunologically as mature as a rabbit at birth and if any direct comparisons of immunological status can be made with a newborn human baby. I shall attempt to offer an answer to such problems.

Asdell⁵ and Witschi⁴ showed quite clearly that small animals (with short gestational periods) take a remarkably uniform time (6.5 days) to reach the primitive streak stage in embryonic development, while larger animals (with longer gestational periods) require 11–19 days. The opossum is born only 6 days after reaching the primitive streak stage, and the hamster after only 9–10 days, so it should not be surprising to find that these are mammals immunologically immature at birth. Asdell⁵ extended his idea to later stages of embryonic development and demonstrated that mammals take a similar percentage time to reach a given morphological stage of early foetal development.

Lymphocytes and Growth Curves

Otis and Brent⁶ compared morphologically equivalent stages of mouse and human embryos and plotted them in gestational times. Using their figure a direct comparison can be made between the first appearance of small lymphocytes in mice and men. These cells have been observed at 7–8 weeks of gestation in the human and between 14–15 days in the foetal mouse³. Such periods of development coincide on the graph and show that lymphocytopoiesis occurs at the same equivalent embryonic age in two species of quite different size, life span and length of gestation. Unfortunately, we lack comparative embryological data for all the species with which we are concerned. This particularly applies to later stages of foetal development. I do not plan, at this stage, to

embark on a comparative morphological survey to obtain age equivalence based on embryonic differentiation: such a method is certainly desirable, but it unfortunately depends on many embryological observations instead of a parameter which is more readily measured, such as body weight.

If the growth curves of foetal body weight of each species could be unified in a common curve, the times of age equivalence for all species could be read from any point on this curve. Brody's classical work⁷ on common post-natal growth curves has been applied to foetal life by Weinbach⁸, who modified Brody's formula

$$W/A = 1 - e^{-k(t-t')}$$

where W is the weight of the foetus at time t , and t' is the age at which the extrapolated curve cuts the age axis (a mathematical approximation to the onset of embryogenesis). In Brody's formula, A was taken as the weight of the mature animal, but in Weinbach's method A is calculated from three equidistant points (w_1, t_1) , (w_2, t_2) and (w_3, t_3) on the foetal body weight/time growth curve using

$$A = \frac{w^2 - w_1 w_3}{w_1 + w_3 - 2w_2}$$

The other constants are calculated from

$$k = \frac{2 \log_e \left(\frac{w_2 - w_1}{w_3 - w_2} \right)}{t_3 - t_1}$$

$$t' = t_1 - \frac{1}{k} \log_e \left(\frac{A + W}{A} \right)$$

From the three constants A , k and t' and the body weights w_1 , w_2 and w_3 , W/A is plotted against $k(t-t')$ for each species. The three values of t in the developmental age range of each animal are obtained from the three corresponding values, on the horizontal axis, of $k(t-t')$.

My first application of this formula to foetal growth—for all species which have been studied immunologically—indicated that although there was good agreement between the equivalent times of onset of immunocompetence between animals with gestational periods of more than 30 days, this group differed in $k(t-t')$ values from animals with short periods of gestation. There was also good agreement with respect to the onset of immunocompetence among members of this second group of animals. For the method to embrace all species of animals a modification had to be made to include those mammals and birds with relatively short gestational periods. Through Zdrodowski's² proposition "that physiological maturity is a necessary criterion for immunological maturity; the fact that an animal is born does not in itself imply that it is immunologically mature", I was led to Tanner's work on growth velocity. Tanner⁹ emphasized that in species such as man and guinea-pigs, with relatively long periods of gestation, there is an increasing gain in weight ("weight velocity") until birth, when there is a change to slower body growth. These species have the highest birth weight relative to their mother's weight. Other species

such as the rabbit, rat, mouse, hamster and chicken are born "too early" and their weight continues to increase during post-natal life. The rabbit is an extreme example—it experiences an overall increase from 20 days of gestation until 40 days after birth¹⁰. The rabbit thus achieves its peak increase in weight at a very similar time (after conception) to the guinea-pig. The daily increase in weight of rats and mice also continues to accelerate after birth; peak growth rate may coincide with the time of weaning. Tanner's work suggests that animals with gestation periods up to 30 days are born before they have had sufficient time to reach a certain degree of physiological maturity, which is not attained until some time after birth. I have taken the end-point, t_3 , of the common growth curve as the time of "peak growth velocity" for all species. For simplicity, I have assumed that animals with periods of gestation greater than 60 days have their "peak growth velocity" at birth. This is based on the substantial evidence assembled by Tanner⁹. A further improvement to Weinbach's formula is to take t_1 as the time of first appearance of small lymphocytes in the thymus. On this basis, the growth curve covers the period of development from the onset of lymphocytopoiesis to the time of peak growth velocity.

Growth constants have been calculated on these criteria³. Data were obtained from sight-fitted growth curves plotted from foetal weights for the chicken¹¹, hamster¹², mouse¹³, rat¹⁴, rabbit¹⁵, opossum¹⁶, guinea-pig¹⁷, cat¹⁸, dog¹⁹, pig²⁰, sheep²¹, cattle²², monkey²³ and man²⁴. Post-natal growth data were obtained from publications about the hamster²⁵, albino mouse²⁶, White Leghorn chicken²⁷, Long-Evans rat²⁷ and rabbit²⁷.

Data for the time of first appearance of small lymphocytes (t_1) in different species, obtained from ref. 3, are given as the figures on the extreme left of the age ranges in Figs. 1 and 2. The time of "peak growth velocity" for animals with short gestational periods was calculated from post-natal growth data and this is expressed at the extreme right of each age scale in Fig. 2. The times of onset of transplantation immunity, γ M-globulin and antibody formation are indicated on each age scale when the information is available.

The value of $k(t-t')$ for t_1 is usually very close to zero (except for the dog). The first appearance of small lymphocytes in the thymus is the beginning of all foetal immunology based on the lymphoreticular system. The age when this occurs is not easy to define accurately, particularly in larger animals, and further study on lymphocytopoiesis may help to remove any discrepancies. The dog seems to warrant further investigation, for the earliest reported lymphocyte in this species appears long before that in the cat, which has a very similar period of gestation.

The times of onset of transplantation immunity and initial reactivity to phytohaemagglutinin are given in Table 1. Transplantation immunity is not easy to measure: it may be defined as the first influx of proliferating small lymphocytes in a graft bed or the time of final rejection of a skin graft. To avoid confusion I have taken the age when allografts are not usually accepted for longer than 15 days as a definition of immunocompetence. This would correspond, in humoral antibody formation, to the early inductive period. A better criterion would be the onset of the lymphoproliferative reaction (usually about 6 days after grafting), but sufficient data are not yet available. Thus the equivalent ages in Table 1 are not directly comparable with time of onset of antibody formation. Examination of $k(t-t')$ values (Table 1) reveals that the

Fig. 1. Age equivalence of foetal primates, artiodactyla, carnivores and guinea-pig. Birth is indicated by ∇ . The figures at each end of the age scales refer to the first appearance of small lymphocytes (t_1) and the approximate time of "peak growth velocity" (t_3). Intermediate figures are the mid-point (t_2) and the times of onset of transplantation immunity, γ M-globulin and antibody production (from data in Tables 1, 2 and 3).

opossum, rabbit, rat, mouse and chicken, and possibly the dog, become immunocompetent at much the same physiological age ($k(t-t') = 0.18-0.43$) and considerably earlier than the sheep (1.04), which is the only large animal to have been skin grafted *in utero*. Data on man and monkey suggest that cellular immunity and resistance to attack by allogeneic cells, respectively, are established at a similar physiological age ($k(t-t') = 0.55-0.60$) as the ability to reject a skin graft in smaller animals. Calves and guinea-pigs have not yet been studied in early foetal life; the need for such an investigation is indicated by their remarkably high $k(t-t')$ values. There is good evidence that foetal guinea-pigs become resistant to viral attack from about 40 days of age³, and from Fig. 1 we can predict that they may become immunocompetent by 30 days of gestation.

Fig. 2. Age equivalence of foetal and post-natal rodents and chicken. Birth or hatching is indicated by ∇ . The figures at each end of the age scale refer to the first appearance of small lymphocytes (t_1) and the approximate time of "peak growth velocity" (t_3). Intermediate figures are the mid-point (t_2) and the times of onset of transplantation immunity, γ M-globulin and antibody production (from data in Tables 1, 2 and 3).

Table 1. ONSET OF TRANSPLANTATION IMMUNITY OR DELAYED HYPERSENSITIVITY

Species	Onset of transplantation immunity* (days post coitus)	Age equivalent $k(t-t')$	References

† Proliferative reaction to phytohaemagglutinin.

‡ Resistance to graft versus host attack.

§ Delayed rejection.

Fewer species have so far been studied for their ability to synthesize γ M-globulin (Table 2). Man and chicken are able to synthesize γ M-globulins at a remarkably early age: $k(t-t') = 0.20-0.29$. These figures suggest that other species, such as the pig and rat, may soon be found to produce γ M-globulins rather earlier in development, particularly if more sensitive methods can be used. The guinea-pig is clearly an appropriate candidate for study—from Table 2 and Fig. 1 we can predict that it might be capable of γ M-globulin synthesis at a time as early as 30 days of gestation.

Table 2. THE EARLIEST APPEARANCE OF γ M-GLOBULIN IN DIFFERENT SPECIES

Species	Earliest γ M-globulin (days post coitus)	Age equivalent $k(t-t')$	References
Man	74	0.29	39
Pig	74	1.05	40
Guinea-pig	58	2.55	41
Rabbit	30	0.34	42
Rat	30	0.60	42
Mouse	24	0.35	42
Chicken	18	0.20	43

More information is available on the onset of antibody production (Table 3). Generally, the results in terms of equivalent ages agree very well. Antibody has been detected earliest in rabbits, mice and chicken, with the rat and opossum not far behind; all these animals produce antibody following antigenic stimulation at a similar physiological age: $k(t-t') = 0.36-0.58$. Active antiphage production in foetal lambs has been detected²⁸ 6 days after injection of phage after 35 days of gestation—one day before the first appearance of lymphocytes³. It is possible to predict from Table 3 that there may be a slightly earlier onset of the ability to produce antibody in cattle, pigs and hamsters as well as man (in view of his capacity to synthesize γ M-globulin at a much earlier age). Foetal dogs and guinea-pigs would clearly merit study. From Fig. 1 it can be predicted that cats become immunocompetent after about 38 days of gestation.

The application of age equivalence to the ontogeny of the immune response is clearly of great potential use. Not only does it make possible the unification of the onset of immunological function in a range of species, but it

can also be used to predict when animals will become immunocompetent in foetal or neonatal life. It is important, however, that such mathematical calculations are closely related to morphological events in development such as the first appearance of small lymphocytes and the time of peak growth velocity.

Prolongation of Skin Allograft Survival with Spleen Extracts and Antilymphocytic Serum

by

L. BRENT

P. J. KILSHAW

Department of Immunology,
St Mary's Hospital Medical School,
London W2

A single dose of splenic extract is sufficient to induce a high degree of specific unresponsiveness to skin allografts in mice if used in conjunction with antilymphocytic serum. The interval between giving the extract and the antiserum is of great importance, and the unresponsiveness appears to be due to tolerance rather than enhancement.

ONLY the induction of specific unresponsiveness is likely to solve the immunological problems of organ transplantation. Because it is well known that, experimentally, tolerance is established much more readily if the antigenic disparity between donor and recipient is relatively small it seems reasonable to suppose that the progress now being made in tissue typing¹ will facilitate the induction of tolerance in organ recipients, provided that suitable methods become available.

It has been shown that unresponsiveness occurs if thymectomized mice treated with antilymphocytic serum (ALS) are injected with very large doses of lymphoid cells², and in a careful series of experiments Lance and Medawar³ have demonstrated that mice with intact thymuses become tolerant after administration of ALS in the first week after grafting and subsequent inoculation of as few as 25×10^6 F₁ hybrid spleen cells. Although these experiments clearly establish the principle that ALS can be used to potentiate tolerance induction, the use of living cells is clinically undesirable: cells most readily available are lymphoid and the recipient is liable to become the victim of a graft versus host reaction^{4,5}. The experiments described here were carried out to determine in mice the conditions in which tolerance induction with cell free extracts can be potentiated by ALS.

Spleen extracts consisting largely of sedimentable membrane fragments are immunogenic when injected intraperitoneally into mice differing from the tissue donor at the "strong" H-2 histocompatibility locus, that is they bring about the accelerated rejection of skin allografts⁶. Given intravenously these extracts are far less immunogenic and may even prolong the life of skin grafts by a few days, but in an H-2 compatible ("weak") donor-recipient combination their administration, by any route, can bring about substantial prolongation⁷. Martinez *et al.*⁸, using somewhat similar extracts, demonstrated that prolonged treatment of mice could extend graft survival: good results were obtained when the antigenic differences between donor and recipient were confined to the male-specific antigen, while in strong combinations only a fairly small effect was observed (three out of seventeen mice having exhibited "acceptance"). We chose to use a relatively crude and simply prepared kind of extract because, for tolerance induction, it is important that there should be no serious loss of antigenic specificities during extraction.

The extraction procedure was based on that described by Medawar^{7,9}, but differed in detail. About 5 g of splenic tissue was pressed through a stainless steel sieve and taken up in 25 ml. of 0.15 M phosphate-buffered saline (PBS), pH 7.4. The suspension was centrifuged at 500g for 10 min and the sediment resuspended in 5 ml. of PBS, to which 2 volumes of distilled water were added. The material was carefully mixed and sedimented at 3,000g for 10 min, and

it was resuspended in 15 ml. of distilled water. Resuspension was achieved by cutting up the gelatinous sediment with scissors, followed by pipetting. After a further spin at 3,000g for 10 min the supernatant was discarded and the sediment resuspended in 7 ml. of distilled water. This material was blended for 6 min in an Ultra-Turrax blender (TP 18/2, Scientific Instruments Ltd), the speed (approximately 10,000 r.p.m.) being determined by position 80 of a variable voltage transformer ('Variac', Gallenkamp). The concentration of salt was now restored to normality by adding 2 M saline and the material was blended for a further 2 min. After centrifugation at 3,000g for 15 min the supernatant was removed and PBS was added to it to give a concentration of 390 mg wet weight of spleen/ml. The pH was increased to 7.4 by the addition, drop by drop, of 0.1 N NaOH (the extract was magnetically stirred) and, finally, heparin (Heparin BP, Boots) was added to give a concentration of 14 U/ml. As the standard dose of this "semi-soluble" extract (SSE) was the equivalent of 250 mg wet weight spleen, mice were injected intravenously with 0.71 ml. containing 10 U of heparin. Extraction was carried out entirely in the cold, and special care was taken to prevent heating when blending. When required, extracts were stored in sealed ampoules at -80°C .

Two pools of ALS were prepared in New Zealand white rabbits using essentially the method of Levey and Medawar¹⁰. Lymph node cells from CBA mice were generally used and care was taken to minimize the degree of contamination with red blood cells. The sera, which were heated to 56°C for 30 min, Seitz-filtered and stored at -20°C in small aliquots, were virtually non-toxic even

Fig. 1. Effect of a single dose of strain A spleen extract (250 mg wet weight spleen) on the median survival time (MST) of strain A skin grafts. The extract was inoculated intravenously into groups of ten CBA males at various times before and after transplantation, with and without ALS (P2). ○—○, Extract+ALS; ●---●, extract only.

when 0.5 ml. was injected intravenously into mice, and absorption with mouse red cells was therefore obviated. Both serum pools had cytotoxic antibody titres exceeding $1:10^4$, but there was some difference in their *in vivo* action in prolonging skin graft survival. ALS (0.5 ml.) was given intraperitoneally on days 2, 4 and 6 after transplantation of a skin allograft.

Induction of Specific Unresponsiveness

Two combinations of inbred mouse strains were used: A→CBA (strong) and C3H→CBA (weak). The median survival times (MST) of grafts transplanted to untreated recipients were 11 and 21 days, respectively; all recipients were 10–16 week old males. The technique of skin grafting was that of Billingham and Medawar¹¹.

Fig. 2. Effect of a single dose of strain A extract inoculated intravenously into CBA males at various times before transplantation of strain A skin and ALS (P2) treatment. ALS (0.5 ml.) was given intraperitoneally on days 2, 4 and 6 after grafting. No treatment (A). Extract inoculated before grafting: 16 days (B); 11 days (C); 6 days (D) and 1 day (E). ALS only (F).

Figs. 1 and 2 give the results of two series of experiments in which SSE prepared from strain A mice was injected into CBA males at various times in relation to skin transplantation. It is apparent (Fig. 1) that SSE inoculation immediately before and after grafting was inefficacious but that a substantial shift in the MST occurred when SSE preceded grafting by 6 days. In another experiment (Fig. 2) pretreatment on day 6 failed to alter the MST although there were more long term survivors, but when the interval was lengthened to 11 days the MST went up to 90 days. By far the best results were obtained with an interval of 16 days, with an MST exceeding 120 days. The six mice in the 16 day group bearing healthy grafts on day 100 received a second strain A graft, and all these were accepted for a minimum of 24 days. Most went on for much longer, and two animals carried their grafts for a further 100 days, when the experiment was terminated. It is worth noting that, when rejection did occur in the other mice, both old and new grafts were affected at roughly the same time.

The longest interval between SSE inoculation and skin grafting investigated so far is 26 days, and the results were comparable with those obtained at 16 days. When experiments with 16 and 26 day intervals were performed in the weak combination, more than 50 per cent of the recipients carried their grafts for more than 150 days, and there is every indication that most of these grafts will be tolerated indefinitely.

In further experiments SSE was routinely injected 16 days before test grafting. The effect was found to be dose-dependent in the strong combination: the extract

Fig. 3. Dose effect of strain A spleen extract inoculated intravenously into CBA males (18–20 mice/group) 16 days before transplantation of strain A skin and ALS (P2) treatment. The extract dose is expressed as mg wet weight spleen: A, 250 mg; B, 25 mg; C, 2.5 mg; D, 0.25 mg; E, ALS only.

from 25 mg still produced a significant effect, whereas 0.25 mg did not (Fig. 3). This experiment also seems to suggest that a dose of 2.5 mg actually undermined, if to a slight extent, the activity of the ALS. In the weak combination the dosage effect was rather less clear cut and good results were obtained with a dose as low as 2.5 mg.

SSE induced unresponsiveness is strain specific. This was demonstrated by two kinds of experiments: (a) syngeneic (CBA) SSE did not prolong the life of strain A grafts (Fig. 4), and (b) the unresponsiveness evoked by strain A SSE did not extend to Balb/c skin grafts (Table 1) although Balb/c mice are thought to carry only a single H-2 antigen absent in strain A.

Possible Mechanisms

The relationship between the time of antigen administration and skin grafting raises the possibility that the unresponsiveness is akin to immunological enhancement,

Fig. 4. Specificity experiment I: comparing intravenous inoculation of strain A and CBA extracts and heparinized saline into groups of nineteen CBA males 16 days before transplantation of strain A skin and ALS (P3) treatment (0.5 ml. on days 2, 4 and 6). ■, A extract; ▲, CBA extract; ●, heparinized saline.

Table 1. SPECIFICITY EXPERIMENT II: INTRAVENOUS INOCULATION OF CBA MALES WITH STRAIN A SPLEEN EXTRACT 16 DAYS BEFORE TRANSPLANTATION OF STRAIN A OR Balb/c SKIN, FOLLOWED BY 0.5 ml. OF ALS (P3) ON DAYS 2, 4 AND 6

Extract	No. of mice	Skin graft	Median survival time (days)
Strain A	5	Strain A	> 50
Nil	7	Strain A	24
Strain A	6	Balb/c	21
Nil	6	Balb/c	22

especially in view of the report¹² that rat kidney allografts can be protected by passive transfer of hyper-immune serum. To sustain such a hypothesis it would be necessary to demonstrate that SSE-injected mice form humoral antibodies against donor strain antigens in adequate amounts. We therefore examined the sera of ten mice at various times before and after skin transplantation for the presence of haemagglutinating antibodies, using the polyvinyl-pyrrolidone technique. The results were uniformly negative, even when some of the grafts were undergoing protracted rejection between 40 and 60 days. (The one possible exception was an animal which gave a dubious titre of 1:8 on day 50, when its skin graft was being rejected.) These negative findings are supported by tests for haemagglutinating¹³, cytotoxic¹⁴ and antigen-binding¹⁵ antibodies on the pooled serum prepared from SSE-injected mice 21 days after skin grafting, at a time when they all bore perfect skin grafts and the grafts on ALS control animals were close to their MST. These tests were again totally negative. Our results are therefore not compatible with an enhancement hypothesis.

Sensitization *per se* is not sufficient to explain the effect. When SSE was substituted by a skin graft, or by lymph node cell suspensions, no comparable effect was obtained (Table 2). Indeed, skin grafts and the higher cell doses completely subverted the action of the ALS, and while this was not true for doses of 10^5 and 10^4 cells none of them raised the MST above that of the ALS controls. Because even 10^4 cells constituted a sensitizing dose in normal recipients experiments with even lower doses are in progress; but at present we must conclude that the physical form of the antigen is vitally important and that only subcellular extracts provide the correct stimulus for specific unresponsiveness to be induced in experiments of this design. It is of considerable interest that liver extracts have been found to have very similar properties, despite the fact that when prepared from perfused livers they are totally non-immunogenic (unpublished work of L. B. and J. A. Hansen).

Several recent publications have been concerned with the possible synergistic effect of spleen extracts and ALS; that only relatively small effects have been uncovered is likely to be due to the fact that the extracts were administered too near the time of skin transplantation. Thus Abbott, Monaco and Russell¹⁶ commenced a prolonged treatment with extracts 1 day before grafting and encountered substantial prolongation of graft survival only in thymectomized mice. Lance and Medawar⁹ found that a single pulse of SSE had no discernible effect when given

in conjunction with ALS, and even when SSE was administered repeatedly every two weeks the MST was not significantly increased (though a small proportion of these mice tolerated their grafts for periods well in excess of the controls).

Assuming that ALS acts on the pool of recirculating lymphocytes (for recent review see ref. 17) and that SSE does not cause cellular proliferation in the central lymphoid organs (an assumption that is being investigated), two possible explanations are suggested to account for our observation that SSE acts more effectively when given well before skin grafting and ALS treatment. First, SSE may mobilize antigen-specific cells from the central lymphoid organs, so that a greater proportion of these cells is eliminated by the ALS; and second, SSE may act on antigen-specific cells by making them tolerant and/or short lived. Both hypotheses, which are by no means mutually exclusive, would explain the time-dependence of the phenomenon.

Clinical Applications

It would be premature to apply this method of inducing specific unresponsiveness to human organ recipients until further experiments have been carried out in species other than rodents and with organ grafts, and before the efficacy of more highly purified extracts has been ascertained. It is, however, encouraging that a synergistic action of tissue extracts and conventional immunosuppressive drugs prolonging the life of kidney allografts in dogs has already been demonstrated¹⁸. The method described here is an advance in that it requires only a limited course of ALS treatment (in clinical terms the total dose of ALS used so far is nevertheless very high) and a single injection with extract (though we have shown with liver extracts that in an H-2 incompatible combination the results can be substantially improved if in addition smaller doses are injected for some time after transplantation (unpublished work of L. B. and J. A. Hansen)). Clinically, the use of liver as opposed to spleen extracts could be advantageous not only because much larger amounts of antigen would be obtained, but also because of the non-immunogenicity of liver extracts (unpublished work of L. B. and J. A. Hansen). The problem of pre-treating patients can probably be overcome by storage of the organ (this is as yet impracticable in most cases) by selection of separate extract and organ donors closely matched for their HL-A antigens, or by using stored extracts covering all major antigens.

We thank Mrs A. V. Thomas and Mr A. G. Bain for technical assistance, and the Medical Research Council for supporting this work. We also thank Dr P. C. L. Beverley of the US National Institute for Medical Research for carrying out tests for antigen-binding antibodies.

Rejection of Skin Allografts by Radiation Chimaeras: Selective Gene Action in the Specification of Cell Surface Structure

by

Use of the technique of acquired tolerance suggests that epidermal cells contain distinctive transplantation allo-antigens—antigens not also possessed by marrow and lymphoid cells.

SEVERAL cell surface alloantigens of the mouse, coded by several independent genetic loci, are expressed exclusively or predominantly on thymocytes and lymphocytes; they have been referred to as differentiation antigens¹. A similar alloantigenic system characteristic of immunoglobulin-forming cells has also been described². One important implication of these newly recognized antigenic systems is that they may aid in the understanding of the way in which cells identify one another and so assemble themselves systematically into biological structures ("cell recognition"). This can be readily envisaged in genetic terms. Selective gene action determines the different patterns of protein synthesis in differentiated cells, and so it should also account for the specialization of cell surface structure, and that for the characteristic properties of surface recognition which cells acquire as a result of differentiation, and which must underlie all forms of multicellular organization.

To strengthen the hypothesis that the programme of differentiation for each cell type includes the genetic specification of a characteristic surface conferring specific mutual cell recognition, we have looked for evidence of differentiation antigens in cells other than those of the lymphoid system. The serological methods which revealed these antigens on lymphoid cells¹ require dispersed viable cell populations for testing with cytotoxic antisera, a technique that is not readily applicable to the cells of tissues such as skin. Although appropriate serological procedures can no doubt be devised, we decided to look first for skin differentiation alloantigens *in vivo*. Our experiments were suggested by reports that chimaerism in man, cattle and mice (and, according to a recent report, in rats also³) does not always guarantee the survival of skin allografts from the donor whose haemopoietic cells continue to colonize the recipient⁴. In other words, immunological tolerance⁵ of haemopoietic cells does not invariably entail permanent tolerance of skin grafts from the same donor, as it might be expected to do if there were no organ-specific alloantigens capable of eliciting a homograft reaction⁶. Analogy with the differentiation antigens of lymphoid cells⁷ prompted the explanation that these rejections were caused by an immune response to alloantigens expressed on the skin of the donor but not on the donor's haemopoietic cells^{7,8}.

We studied chimaeras formed by protecting lethally irradiated mice with bone marrow or spleen cells because

in chimaeras of this type the recipient's haemopoietic system is totally replaced by the donor's (as far as this can be determined), making it easy to prove chimaerism by typing red cells⁹ or lymphocytes¹⁰ for donor H-2 antigen. Our choice of the combination (C57Bl/6 × A)F₁ donor and C57Bl/6 recipient (*abbr* C57) was based on reported observations that A strain recipients that had been inoculated at birth with (CBA × C57)F₁ cells rejected C57 skin but not CBA skin ("split tolerance")¹¹. Accordingly, strains C57 and A (but not CBA and A) can be considered to carry different alleles at a locus specifying a differentiation alloantigen of skin. The purpose of using F₁ rather than A strains donors of spleen and bone marrow cells was to avoid graft versus host reactions. Fig. 1 summarizes the results of our several experiments with this donor-recipient combination.

Course of Rejection

The twenty-three mice in group 1 received A strain skin grafts 11 weeks after irradiation. They rejected them about as rapidly as if there had been H-2 incompatibility. The rejection of second-set A strain and (C57 × A)F₁ skin grafts in the same animals was accelerated. Later, all these mice were shown to be chimaeric by H-2 haemagglutination and by cytotoxic tests on lymphocytes obtained by excising an inguinal lymph node under sodium pentobarbital anaesthesia (Table 1). In these tests, and all other such tests we have carried out on radiation-chimaeras of this type, both in these and other experiments, it has been impossible to detect any erythrocytes or lymphocytes of recipient type. Thus, although it cannot absolutely be excluded that rejection was brought about by a small undetectable fraction of immune cells of recipient origin, it seems more likely that the cells responsible were donor cells that had lost their immunological tolerance of A strain skin alloantigen after being transferred to C57 recipients which had a different skin alloantigen allele. We infer that maintenance of self-tolerance to skin alloantigen was lost when the immunocompetent cell population was removed from the environment where this antigen is normally present (compare ref. 12).

Each of the ten mice in group 2 was restored with spleen cells from a single (C57 × A)F₁ splenectomized donor which then provided a skin graft for the same recipient 5 weeks later. The rejection of these grafts shows that

Table 1. H-2 TYPING OF ERYTHROCYTES AND LYMPHOCYTES OF CHIMAERAS

	Haemagglutination test ^a						Cytotoxic test ¹⁰			
	H-2 ^b anti H-2 ^a 1:16	H-2 ^b anti H-2 ^a 1:64	H-2 ^b anti H-2 ^a 1:256	H-2 ^b anti H-2 ^a 1:20	H-2 ^a anti H-2 ^b 1:80	H-2 ^a anti H-2 ^b 1:320	H-2 ^b anti H-2 ^a 1:40	H-2 ^b anti H-2 ^a 1:80	H-2 ^a anti H-2 ^b 1:40	H-2 ^a anti H-2 ^b 1:80
(C57 × A)F ₁ → C57 chimaeras*	+++	+++	+++	+++	+++	+++	> 95	> 95	> 95	> 95
Normal control mice	+++	+++	+++	+++	+++	+++	> 95	> 95	> 95	> 95
(C57Bl/6 × A)F ₁	++	++	++	++	++	++	> 95	> 95	> 95	> 95
C57	++	++	++	++	++	++	< 10	< 10	< 10	< 10
A	+++	+++	+++	++	++	++	> 95	> 95	< 10	< 10

* Every irradiated C57 mouse restored with (C57 × A)F₁ cells and tested with H-2 antisera by haemagglutination or cytotoxicity for the presence of donor cells gave the results shown here, which are indistinguishable from the normal (C57 × A)F₁ control. Thus erythrocytes and lymph node lymphocytes of recipient origin were either absent or were present in numbers too few to be detected.

The usual serological controls, omitting antibody or complement, were invariably negative. As a further test of serological specificity, cytotoxic tests were performed with the serum (C57 × A)F₁ anti C3H (anti H-2.32); reaction with lymph node lymphocytes of normal H-2^k mice was strongly positive, but there was no reaction with lymphocytes of the chimaeras, indicating that the latter are not abnormally sensitive to non-specific lysis by mouse serum and guinea-pig serum (source of complement).

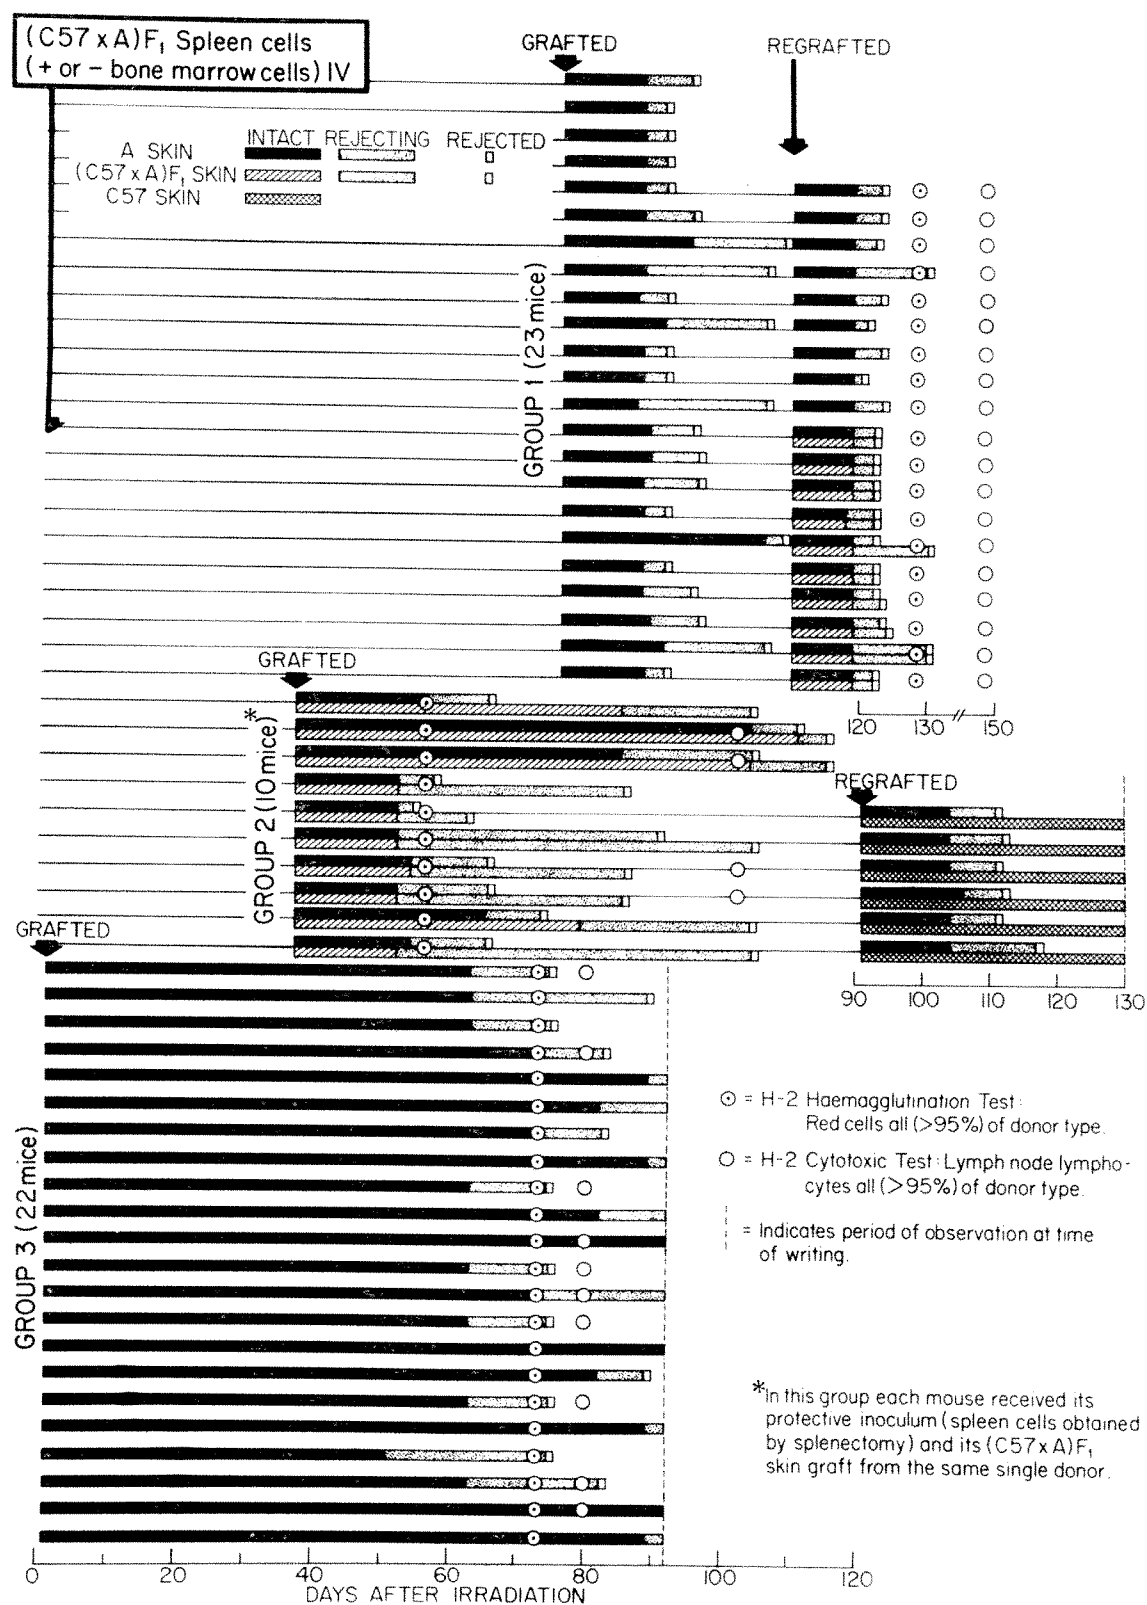

Fig. 1. Summary of experiments in which lethally irradiated C57 mice, restored with (C57 x A)_F₁ haemopoietic cells, were grafted with A strain and (C57 x A)_F₁ skin. Protective inocula (given intravenously within 24 h of irradiation) were: for group 1, pooled bone marrow and spleen cells (5×10^7 /mouse); for group 2, each mouse received (2 to 6×10^6) spleen cells (obtained by splenectomy) from a single (C57 x A)_F₁ donor, which also provided the (C57 x A)_F₁ skin graft for the same individual recipient 5 weeks later; for group 3, pooled spleen cells (5×10^7 /mouse). In group 1 the recipients, and the donors both of haemopoietic cells and of skin, were females. In groups 2 and 3, all were males. Total body irradiation (750 r) was delivered from a 'Maxitron 300' (General Electric) X-ray machine (HVL 2 mm Cu); control irradiated mice receiving no protective inoculum invariably died within 30 days. Terramycin (Pfizer) was included in the drinking water, and Kanamycin (Bristol Laboratories) was administered intramuscularly, for 3 weeks after irradiation. Skin from the tail was grafted by the method of Billingham and Medawar¹⁴; double grafts, A and (C57 x A)_F₁ were placed side by side in the same bed. All mice were obtained from our own breeding colonies (origin: C57Bl/6J and A/J); recipients were 10-13 weeks old at the time of irradiation.

rejection cannot be explained by genotypic differences between the donors of the skin grafts and the donors of the cells producing chimaerism. We infer that the antigenic difference between haemopoietic cells and skin cells is phenotypic and is a consequence of selective gene action¹.

The twenty-two mice in group 3 were grafted with A strain skin within 24 h of irradiation, shortly after receiving their protective inoculum of spleen cells. The survival of these grafts was considerably longer than that of grafts in groups 1 and 2 where grafting was delayed for 11 and 5 weeks respectively. On present evidence it is not possible to say whether this is due to immunosuppression following irradiation, or whether several weeks is required for the expanding population of donor cells to lose its tolerance of the A strain skin alloantigen from which it is separated. In any case, there was rejection, showing that a skin graft was not sufficient to maintain the presumed initial tolerance of the donor population. Possibly immediate grafting postpones loss of tolerance, for the prolongation of graft survival in group 3, in comparison with group 2, was more than the 5 weeks which elapsed between irradiation and skin grafting in group 2. But groups 2 and 3 are not strictly comparable because they were irradiated on different occasions, the former received two grafts and the latter one, and they received different numbers of spleens. The idea that early grafting partially sustains tolerance is therefore no more than a suggestion to be pursued in further experiments.

The serum of chimaeras that rejected A or (C57 × A)F₁ skin grafts has been tested stringently for cytotoxic antibody to normal A strain thymocytes or lymphocytes with negative results.

In other experiments lethally irradiated A strain female mice were restored with (C57 × A)F₁ female bone marrow and spleen cells, and were grafted 11 weeks later with C57 female skin. Survival of the grafts was much longer, and rejection more protracted, than in the foregoing experiments; ten out of twenty-one of the recipients (proven chimaeras) rejected C57 skin within 170 days of grafting. In another donor-recipient combination, (BALB/c × DBA/2)F₁-to-DBA/2, five out of twenty-one recipients (similarly irradiated and restored, but not tested for chimaerism) rejected BALB skin grafts within 250 days.

The explanation proposed for all these rejections may apply also to cases of late rejection of skin allografts

which have been attributed previously to loss of chimaerism with increasing age¹³. Similarly, in the case of donor-host combinations where inoculation of haemopoietic cells into neonatal recipients characteristically fails to induce tolerance of donor skin grafts, it may be that the explanation lies in a strong skin alloantigen, rather than in failure to establish chimaerism.

The special value of the (C57 × A)F₁-to-C57 combination is the feasibility of securing skin graft rejection in 100 per cent of chimaeric recipients. Thus the genetic experiments required to define the locus or loci responsible for specifying skin alloantigen will be greatly facilitated.

We thank Dr John S. Laughlin and Richard G. Evans for their help and Miss Lee Hubbard, Miss Chika Iritani and Miss Barbara Goldberg for technical assistance. This work was supported in part by grants from the John A. Hartford Foundation, the US National Cancer Institute and the National Institute of Allergy and Infectious Diseases.

Soluble cell membrane extracts of liver and spleen have been injected intravenously at the time of renal allografting. In dogs and rhesus monkeys there was slight prolongation of transplant survival in some experiments. Survival was markedly prolonged in 30 per cent of pigs, however. Donor blood and serum had a similar effect in protecting porcine liver allografts from rejection.

LIVER allograft rejection has been reported in dogs^{1,2}, rats³, pigs⁴⁻⁷, rhesus monkeys⁸ and man^{7,9}, but in each of these species livers are rejected less vigorously, or can be retained more easily with immunosuppressive agents, than are allografts of other organs and skin. In our

experience orthotopic liver allograft rejection in the pig has been mild or minimal in animals given no immunosuppressive treatment observed up to 2.5 years¹⁰⁻¹². We have transplanted livers orthotopically between litter mates, within strains of pigs which have been partially

line bred, and across three distinct breeds—large white landrace and wessex saddleback. In each case liver allograft rejection consisted of no more than slight infiltration of the portal tracts with mononuclear cells and a variable increase in fibrous tissue. There have been no severe destructive lesions of the hepatic parenchyma. We have been unable to detect recipient lymphocyte entrapment in liver allografts, nor release of large amounts of enzymes from the liver. Postoperative concentrations of cortisol and corticosterone in the serum have been normal. It is our impression that a short operating time and minimal hepatic ischaemia correlate directly with less histological evidence of rejection. In marked contrast similar categories of pigs usually react vigorously against skin, heart and kidney allografts producing destructive rejection between 5 and 10 days. Mixed lymphocyte culture reactions between such pigs are generally positive¹³, with the exception of tests between 25 per cent of litter mates¹⁴. In some experiments, after liver allografting, specific long lasting depression of the mixed lymphocyte reaction of recipient cells against the donor was observed, a pattern that would be expected in a tolerant animal^{15,16}. In other experiments stimulation persisted at the same or an increased level without the organ being rejected¹³. If the *in vitro* proliferative response parallels *in vivo* immune mechanisms, then stimulation failing to lead to organ rejection could be a consequence of an ineffective cellular response or protection of the graft by enhancing antibody. Partial tolerance and enhancement are not necessarily mutually exclusive¹⁷⁻¹⁹.

Both orthotopic and auxiliary liver allografts confer marked protection from rejection on simultaneously transplanted kidneys from the same donor. This renal allograft protection has persisted after removal of the auxiliary liver 24 h after transplantation¹². Because liver allograft protection from rejection has always been greater for tissues from the same donor than from third party animals, transplantation antigens must be involved. Usually third party grafts are rejected at the expected time, although occasionally survival has been prolonged. Chance sharing of transplantation antigens between the third party animal and the liver donor and/or the recipient is a possible explanation. In view of the variability of third party graft survival, antigen sharing would seem to be more likely than an additional non-specific effect of the grafted liver, although there is evidence of non-specific protection in classical tolerance²⁰.

We have suggested that the allografted porcine liver can induce partial immunological tolerance in animals with competent immune systems¹². The initial effect is too rapid for antibody production, but a later contribution of specific enhancement has not been excluded. It is possible that the porcine liver produces transplantation antigens in a tolerogenic form¹¹. In sympathy with this hypothesis was the demonstration of HLA antigens in the albumen fraction of human serum by Van Rood²¹. We have repeated and confirm these findings and have made similar observations in the pig (unpublished observations of D. W. and V. C. J.). Preliminary investigations suggested that soluble liver cell membrane preparations in the pig had immunosuppressive activity¹². The experiments reported here were designed to investigate this hypothesis further. The effects of soluble cell membrane extracts from liver and spleen on renal allograft survival have been studied in the pig, dog and rhesus monkey. In pigs further observations have been made on animals with renal allografts treated with donor blood or serum.

Preparation of Antigen

Fresh spleens and livers were separately disaggregated by passing through a mechanical tissue grinder and then gently homogenized to give cell suspensions. These were extracted by hypotonic lysis²², and the cell residue was separated from the extracted material by centrifuging at

500g. This supernatant was centrifuged at 85,000g for 90 min and the deposit resuspended at 2 per cent in water saturated with thymol and stored at 4° C. This was a crude membrane fragment preparation.

Soluble antigen was obtained by incubation of this material at 37° C in 0.05 M Tris buffer, pH 7.5, for 2.5 h and centrifuging at 150,000g for 2 h. The supernatant was concentrated to one-tenth of its volume and put aside. The sediment was resuspended at 2 per cent w/v and incubated with papain (activated with cysteine) at 37° C for 60 min; this was cooled, sodium iodoacetate added as inhibitor, and centrifuged at 150,000g for 2 h. The supernatant was concentrated and passed through a 'Sephadex G-75' column to remove papain. The excluded fraction was added to the supernatant previously obtained following incubation with Tris buffer alone. The pooled material was adjusted to 10 mg/ml. of protein, passed through a 'Millipore' filter (3 µm) and stored at -50° C until used.

This kind of material has been referred to as "crude soluble antigen" and, as such, was used in most of the experiments described. For a few experiments crude soluble antigen was purified by passing through 'Sephadex G-200' columns, where the intermediate (retarded) fraction was used. This fraction contains H-2 or HLA active material when this procedure is applied to mouse or human material respectively²³⁻²⁵.

Surgical Technique

Pigs weighing 30-40 kg, of either sex, were used as recipients; donor animals were larger. Under halothane anaesthesia with spontaneous respiration the abdominal cavity was opened and the animals were heparinized. The left kidney of the donor was transplanted orthotopically to the bed of the recipient's left kidney after nephrectomy. The renal artery with a Carrel patch of aorta was anastomosed to the side of the recipient's aorta. The renal vein and ureter of donor and recipient were joined end to end²⁶. Penicillin (300 mg) and streptomycin (0.5 g) were given by intramuscular injection and 500 ml. of normal saline was infused into a neck vein. No drugs were given postoperatively.

Experimental Groups

(1) Control renal allografts were given to thirty-one animals. Seventeen had both their own kidneys removed at the time of grafting and died after between 5 and 33 days (Fig. 1). Ten of the thirty-one grafts were between litter mates, and nine of these were moderately to severely rejected. One allograft was normal at autopsy after 12 days. The other twenty-one recipients died or had their allografts removed after between 6 and 25 days. All of these grafts had substantial to severe rejection. The relationships of donor and recipient were: three half-sibs,

Fig. 1. Survival of seventeen bilaterally nephrectomized pigs with renal allografts. Nine transplants were between litter mates. These recipients survived 5, 7, 9, 10, 11, 12, 15, 20 and 33 days.

one distant relative, eight unrelated pigs and nine of a different breed.

(2) Seventeen of the bilaterally nephrectomized pigs with renal allografts treated with soluble cell membrane extracts at the time of operation (Table 1) survived beyond 4 days (Fig. 2). None of these transplants were between litter mates. Eight pigs died after 8–29 days with rejected kidneys. The relationships of donor and recipient were five distant relatives, two unrelated and one of a different breed. Five animals with unrelated donors died after 36–156 days with rejected kidneys. Four were alive after 105–258 days. The relationships of donor and recipient were one half-sib, one distant relative and two unrelated.

Reasons for Little Rejection in Pig

Why we have found porcine orthotopic liver allograft rejection to be consistently so minimal is not clear. Minor technical points or the pig types we have used could be relevant, but in view of the conventional rapid rejection of other allografted tissues, the usually positive mixed lymphocyte culture reactions and the variety of pig breeds used, close histocompatibility between donor and recipient is an untenable explanation. An unlikely possibility is that certain strong transplantation antigens present in some strains of pigs are absent in the three breeds we have used. Even if this was the case, there is sufficient histoincompatibility between our pigs to produce aggressive rejection of all tissue so far allografted with the exception of the liver. Thus the behaviour of porcine hepatic allografts in contrast remains remarkable and must indicate a phenomenon of biological significance. More con-

sistent with the observations is the proposition that pigs vary in the amount and/or type of transplantation antigens produced by the liver. This might be influenced by environmental factors. It is not known if this is a unique property of the pig. Certainly the difference between liver and other organ allograft rejection in the dog, rat and several primate species is far less than in the pig^{1-3,7,9}. The 7 month survival, however, of one of our rhesus monkeys, which was given no immunosuppressive treatment, contrasts markedly with the behaviour of the other organ grafts, which in this species are usually rejected promptly⁸. Soluble transplantation antigens given intravenously possibly have more effective access to the lymphoid system in the pig than in other species because of peculiarities of porcine lymphocyte circulation and lymph node structure^{27,28}.

The immunosuppressive effect of soluble cell membrane extracts of donor liver and spleen has been unimpressive in the dog and rhesus monkey. In the pig, however, the prolongation of renal allograft survival has been comparable with that produced by a liver allograft. Specificity has not been investigated. In all but one experiment membrane extracts were prepared from the kidney donor. One pig survived nearly 9 months on a renal allograft from a donor unrelated to the animal from which the cell membrane extract was prepared. This does not exclude a specific mechanism, which could have resulted from sharing transplantation antigens between the membrane extract donor and kidney donor. Further studies with third party membrane extracts should help to clarify this point. There was no obvious difference in the effects of soluble cell membrane extracts prepared from liver or spleen, nor were the rate and route (intravenous or intraportal) of infusion apparently significant. A dose response relationship in terms of weight of protein and immunosuppressive effect was not established. The prolongation of renal allograft survival in animals treated with donor blood or serum is consistent with the proposition that soluble tolerogenic transplantation antigens can be present in normal pig serum.

These experiments on pigs are compatible with the hypothesis that soluble transplantation antigen can induce partial tolerance to renal allografts in immunologically competent pigs. It should, however, be emphasized that definitive proof is lacking. When well defined porcine tissue typing sera are available it should be possible to determine whether the cell membrane extracts do contain transplantation antigens and, if so, quantitative experiments could be performed. Then it would be

necessary to demonstrate that liver allografts release into the circulation similar soluble antigens capable of prolonging renal allograft survival.

This work was supported in part by a grant from the Medical Research Council. We thank the Department of Medical Illustration, Addenbrooke's Hospital, Cambridge, for the figures and Dr R. D. Keynes and the staff of the ARC Institute of Animal Physiology, Babraham, for facilities.

RNA Polymerase Mutants blocked in Sporulation

Harvard University

A class of RNA polymerase mutants of *B. subtilis* fails to sporulate. The same mutational alteration prevents the change in template specificity of the enzyme characteristic of sporulating wild-type cells, suggesting that this change plays an essential part in the sporulation process.

It has recently been shown that after infection of *Escherichia coli* by phages T4 (refs. 1 and 2) specific changes occur in the protein subunits of RNA polymerase that determine template specificity of the enzyme. These changes are responsible for the expression of certain

phage genes and possibly for the turn-off of host genes. The discovery that the template specificity of RNA polymerase becomes altered during spore formation in *Bacillus subtilis*³ suggested a similar mechanism for the control of gene expression during the intracellular differ-

entiation that sporulation represents. We demonstrated that sporulation is accompanied by loss of ability of RNA polymerase to transcribe the DNA of phage ϕ *in vitro*, a finding consistent with the known inability of this phage to grow or to induce phage-specific enzymes in sporulating cells⁴. We proposed that this change in template specificity might control, at least in part, the switchover from expression of "vegetative genes" to expression of "sporulation genes"^{5,6}. It seemed possible that vegetative *B. subtilis* RNA polymerase would undergo structural modification, including alteration or replacement of a σ factor component; the resulting "sporulation" enzyme would be unable to transcribe either the phage ϕ DNA genome or bacterial genes coding for vegetative proteins, that is, proteins synthesized exclusively in growing cells. In confirmation of this hypothesis experiments described in the following article⁸ show that transcription of phage ϕ DNA *in vitro* is dependent on an RNA polymerase σ factor of molecular weight 57,000 and show that the change in template specificity during sporulation is accompanied by a modification in the structure of a β subunit of the enzyme. Kerjan and Szulmajster⁹ and Avila *et al.*¹⁰ also found that *B. subtilis* RNA polymerase depends on a σ factor for transcription of coliphage T4 DNA and *subtilis* phage ϕ 29 DNA, respectively.

The drug rifamycin and its analogue, rifampicin, are known to act directly on RNA polymerase from both *E. coli* and *B. subtilis*^{11,12}. Here we report that among rifampicin-resistant (*rfr*) mutants of *B. subtilis* there is a frequent class of mutants that, in a single mutational event, has gained drug-resistance *in vivo* and *in vitro* and lost the ability to sporulate. This mutation prevents the change in template specificity of RNA polymerase characteristic of sporulating wild-type cells, indicating that this change is a critical step in the sporulation process.

Isolation of *rfr* 10

We have shown earlier that the component of *B. subtilis* RNA polymerase determining sensitivity to rifampicin is conserved during sporulation³. This was concluded from a study of the properties of the mutant *rfr* 11, which is resistant to rifampicin *in vivo* and produces a mutant RNA polymerase that is drug resistant in extracts of both log-phase and sporulating cells. *Rfr* 11 is not impaired in spore production (phenotype *rfr*⁺ *sp*⁺; see Table 1).

A second RNA polymerase mutant, called *rfr* 10, was found to have gained resistance to rifampicin and simultaneously lost the ability to sporulate. *Rfr* 10, like *rfr* 11, was selected after ultraviolet mutagenesis of *B. subtilis* 3610 as a young colony able to grow on tryptose blood agar base (Difco) plates containing 5 μ g/ml. rifampicin (Ciba). When tested for sporulation by phase-contrast microscopy after growth for 24 h at 37° C in the standard conditions^{3,4}, only 5 per cent of the surviving cells contained spores as compared with over 95 per cent in the

normal strain (see Table 1). Thus the phenotype of *rfr* 10 is *rfr*⁺ *osp*⁻ (*osp*=oligosporogenous, that is, deficient in sporulation but producing spores at a frequency higher than the genetic reversion rate¹³).

Characterization of *rfr* 10

As shown in Table 1, mutant *rfr* 10 is resistant to rifampicin *in vivo*; growth is normal both in liquid medium and on plates containing rifampicin. On solid media favouring sporulation, *rfr* 10, like many mutants defective in sporulation, forms light-coloured, wet colonies¹⁴. *Rfr* 10 is not dependent on the presence of rifampicin for growth.

Extracts of logarithmically growing cells of *rfr* 10 were made by the method previously described³, which entails sonication, centrifugation at 100,000*g*, and precipitation of RNA polymerase from the supernatant with ammonium sulphate at 60 per cent saturation. As shown in Table 2, RNA polymerase from *rfr* 10 is resistant to rifampicin *in vitro*. An unexpected finding was that these extracts were poorly active with the synthetic template poly dAT, recalling the reduced ability of extracts of sporulating cells of *rfr* 11 to transcribe poly dAT (Table 2 and ref. 3).

Table 2. ACTIVITY OF RNA POLYMERASE EXTRACTED FROM *rfr* MUTANTS

Strain	Specific activity with ϕ DNA				Specific activity with poly dAT			
	Log-phase -rif	Log-phase +rif	Sporulating phase -rif	Sporulating phase +rif	Log-phase -rif	Log-phase +rif	Sporulating phase -rif	Sporulating phase +rif
3610	17.2	0.1	0.3	—	6.3	0.1	10.6	0.3
<i>rfr</i> 11	17.9	19.2	0.25	—	7.85	7.4	2.8	3.0
<i>rfr</i> 10	14.6	15.5	3.4	3.9	0.8	—	1.3	—
<i>rfr</i> 10 rev 8	15.7	5.2	0.86	0.50	2.0	1.4	2.2	0.84
<i>rfr</i> 3Y	13.8	11.0	8.7	7.3	4.4	4.3	0.7	0.7

For each strain, RNA polymerase was prepared by sonication, high-speed centrifugation, and precipitation with ammonium sulphate at 60 per cent saturation as previously described³ from cells harvested either in mid-log phase or 5 h after the end of logarithmic growth ("sporulating phase"). Medium 121B and the synchronized culture system of A. L. S. and Roscoe⁴ were used throughout. Enzymes were assayed as previously described³ with either phage ϕ DNA or poly dAT as template and, where applicable, in the presence of 0.4 μ g/ml. rifampicin or rifamycin. One unit of activity is that amount of enzyme that incorporates 1 nmole of ¹⁴C-AMP in 10 min. Specific activity is in units/mg protein.

RNA Polymerase from Cells of *rfr* 10 in Stationary Phase Cells transcribes ϕ DNA

The fact that *rfr* 10 does not sporulate with the same efficiency as wild-type *B. subtilis* suggested the possibility that RNA polymerase from *rfr* 10 might not undergo the same change in template specificity as the wild-type enzyme. To test this possibility, extracts were prepared from cells in mid-log phase and at several points in stationary phase, including times at which wild-type cells would completely exclude phage ϕ growth and produce an RNA polymerase completely inactive with phage ϕ DNA *in vitro*^{3,4}. Samples were also taken for measurement of phage burst size.

As shown in Fig. 1, RNA polymerase from *rfr* 10 was active with phage ϕ DNA at all times tested and the pattern of specific activity closely followed the pattern of phage burst size. Table 2 shows that polymerase activity with phage DNA as template was rifampicin-resistant in late stationary phase extracts as well as in log-phase extracts. A mixture of the log-phase extract with that of the last time-point (7.3 h) gave an activity equivalent to the sum of the individual activities of the two extracts. At all times tested, RNA polymerase from *rfr* 10 had low activity with the synthetic polymer poly dAT.

The finding that a mutation in RNA polymerase can block spore formation without affecting vegetative growth implies that the mutated component plays a specific part in sporulation. That the same mutation prevents the change in template specificity characteristic of sporulating wild-type cells suggests that it is this

Table 1. SPORE FORMATION AND RIFAMPICIN-RESISTANCE OF *rfr* MUTANTS

Strain	Growth in liquid		Colony formation Fraction of resistant cells	Spore formation Fraction of refractile heat-resistant cells	
	-rif	+rif		-rif	+rif
3610	+	—	10 ⁻⁶	0.90	1.0
<i>rfr</i> 11	+	+	0.78	0.95	1.0
<i>rfr</i> 10	+	+	1.0	0.05	0.08
<i>rfr</i> 10 rev 8	+	+	4 × 10 ⁻³	0.90	1.25
3Y	+	+	1.1	0.001	10 ⁻³

Each strain was transferred to medium 121B² (± 5 μ g/ml. rifampicin) after overnight growth in medium 121A². Growth was scored after 24 h of incubation at 37° C. For colony formation, cultures grown overnight in medium 121A were diluted and spread on plates of nutrient broth agar¹⁷ with or without 5 μ g/ml. rifampicin. Plates were incubated overnight at 30° C. Spore formation was tested in two ways. The culture grown for 24 h in medium 121B was examined for refractile spores by phase-contrast microscopy and an aliquot of the same culture was heated to 80° C for 10 min before being diluted and plated on nutrient broth agar; a control was plated before heating. The number of spores produced by strains *rfr* 11 or *rfr* 10 was not affected by the presence of 5 μ g/ml. rifampicin.

change itself that is decisive in determining ability to sporulate.

Rfr 10 Phenotype arises from Single Mutation

Three approaches served to confirm that the *rfr* 10 phenotype is the result of a single mutation: the spontaneous reversion frequency to the phenotype *rfr*⁺ *sp*⁺ was determined, the properties of the revertants were studied in detail, and additional mutants of the *rfr*⁺ *sp*⁻ class were isolated without mutagenesis.

Revertants of mutant *rfr* 10 were obtained by selecting for cells that had regained the ability to sporulate. A single colony of *rfr* 10 was suspended in sporulation medium 121B (see ref. 4) and shaken for 24 h at 37° C. The spores, a small proportion of the population, were isolated by washing the cells in distilled water and layering an aliquot of the washed cells on a linear gradient of 'Renografin 76' (Squibb; see ref. 15) constructed so that spores and vegetative cells would be separated on the

to rifampicin with the ability to sporulate. A representative of this class, *rfr* 10 *rev* 8, was chosen for further study.

Properties of *rfr* 10 *rev* 8

The revertant *rfr* 10 *rev* 8 was sensitive to rifampicin (and rifamycin) in both liquid and solid media (see Table 1). In the absence of the drug, this strain seemed to produce as many refractile, heat-resistant spores as the wild-type strain, but small differences in spore production would not be detectable.

Extracts of *rfr* 10 *rev* 8 were prepared as usual from log-phase and sporulating phase cells and tested for ability to transcribe phage ϕ e DNA and poly dAT and for sensitivity to rifampicin *in vitro*. Log-phase extracts were partially sensitive to rifampicin at the concentration used and had regained the ability to transcribe poly dAT (Table 2). Extracts of sporulating cells were also sensitive to rifampicin with the synthetic polymer as a

Fig. 1. Time course of change in template specificity in *B. subtilis* 3610 and mutant *rfr* 10. Cells were grown in 2 l. of medium 121B using the synchronized culture system of A. L. S. and Roscoe⁴. *a*, At the indicated times, 450 ml. samples were harvested, extracts were made as previously described³, and the activity of RNA polymerase was determined with phage ϕ e DNA or poly dAT as template as previously described³. Specific activity is defined in the legend to Table 2. *b*, At the indicated times, 0.9 ml. samples of each culture were infected with phage ϕ e at multiplicity less than 0.1 and average burst sizes were determined⁴. The end of logarithmic growth (t_0), the presumed starting point for sporulation, is shown by arrows.

basis of their respective densities. Of the single colonies derived from streaking the purified spores on nutrient agar plates, most gave the same small percentage of spores as the parent *rfr* 10 strain when regrown in medium 121B. These spores, which were resistant to plating on rifampicin-containing agar, were not genetic revertants, but rather a reflexion of the leakiness of the mutation.

A second class of spores gave rise to cultures that sporulated normally when regrown in medium 121B and were true revertants for the *sp* character. When tested for resistance to rifampicin, these strains showed the same sensitivity to the drug as wild-type *B. subtilis* 3610, indicating that the *sp* and *rfr* markers can revert simultaneously. The frequency of true revertants was 10^{-5} to 10^{-6} , a value consistent with reversion at a single mutated site. A similar frequency was found by searching on sporulation agar for dry, brown colonies¹⁴ derived from plating a 24 h culture of *rfr* 10 preheated to 80° C for 10 min. Some of the simultaneous revertants for both phenotypes did not completely regain sensitivity

template. More important, as a result of the reverting mutation, *rfr* 10 *rev* 8 lost the ability to transcribe ϕ e DNA during sporulation, a characteristic of wild-type cells. Fig. 2 compares the template activity of RNA polymerase from late stationary phase cells of wild-type, *rfr* 10, and *rfr* 10 *rev* 8. The revertant is altered in all of the properties that distinguish *rfr* 10 from the wild-type strain, strongly suggesting that these characteristics are the result of a single mutation.

Spontaneous *rfr*⁺ *sp*⁻ Mutants

Because *rfr* 10 had been isolated after ultraviolet mutagenesis, additional, spontaneous mutants of the *rfr*⁺ *sp*⁻ phenotype were sought. Single colonies of *B. subtilis* 3610 were grown overnight in medium 121A and spread without dilution on plates of LB agar (ref. 16; agar concentration, 2 per cent) or nutrient broth agar¹⁷ containing 5 μ g/ml. rifampicin or rifamycin (Lepetit). After overnight incubation at 30° C, a representative *rfr*⁺ colony from each clone was picked, purified by

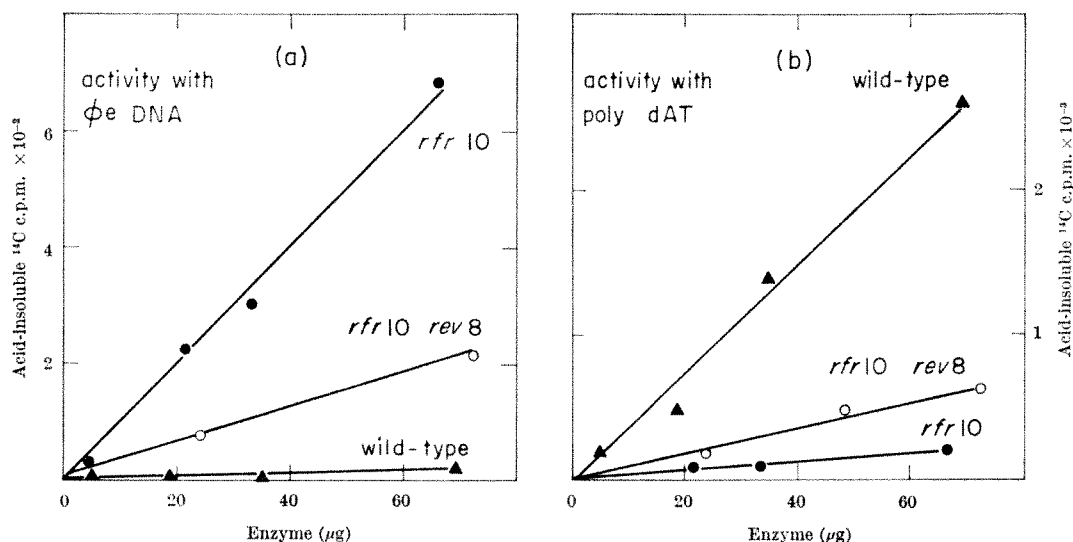

Fig. 2. Template activity of RNA polymerase from late stationary phase cells of 3610, *rfr* 10, and *rfr* 10 *rev* 8. RNA polymerase was prepared from cells of 3610, *rfr* 10, and *rfr* 10 *rev* 8 harvested 5 h after the end of logarithmic growth³. Each extract was assayed at varying protein concentrations with (a) ϕ DNA or (b) poly dAT as template as previously described³.

streaking on drug-containing agar, and tested for sporulation by growth in medium 121B. In three separate experiments, the frequency of the sporulation-deficient class among the *rfr* mutants was four of ten, one of three, and one of five. In all cases, the frequency of the *rfr* phenotype for individual clones was 10^{-7} to 10^{-8} . This result again indicates that the *rfr* *sp*⁻ phenotype can be the result of a single mutation.

One of these spontaneous mutants, termed *rfr* 3Y, was particularly interesting. It is only slightly leaky in spore production (see Table 1). During stationary phase, its RNA polymerase retains more than 50 per cent of the ability of the log-phase enzyme to transcribe phage ϕ DNA (Table 2); ability to transcribe poly dAT is lost specifically during stationary phase.

Rfr Mutants and Sporulation

The finding that some *rfr* mutants do not sporulate indicates that mutations in RNA polymerase can affect sporulation specifically, for these mutants are not altered in vegetative growth. This conclusion implies that RNA polymerase normally plays a part in differentiating between growth and sporulation, a role interfered with by this mutation.

Rfr mutations in *E. coli* are known to be localized in the core of RNA polymerase^{11,18}, that part of the enzyme which remains after selective removal of the σ factor⁷. Rabussay and Zillig¹⁹ have recently shown that the β protein component of the core enzyme is altered in at least one *rfr* mutant of *E. coli*. In the *B. subtilis* system we have shown that the core enzyme is sensitive to rifampicin (unpublished observations). In a following article⁸ we present evidence that sporulation core contains a 110,000 dalton subunit in place of one of the two 155,000 dalton β polypeptides of vegetative core and suggest that this alteration is responsible for the loss of ability of RNA polymerase to transcribe ϕ DNA. It is tempting to speculate that RNA polymerase in *rfr* 10 and *rfr* 3Y cells retains the ability to transcribe ϕ DNA during stationary phase because it is unable to undergo this alteration.

That a single mutation in RNA polymerase can prevent both sporulation and the change in template specificity demonstrates that these two phenomena are inter-related. The loss of vegetative template specificity may

be responsible for the turn-off of vegetative genes during sporulation; *rfr* 10 and *rfr* 3Y may fail to sporulate because they continue to express vegetative genes during stationary phase or because they fail to express sporulation genes. Consistent with this hypothesis is the finding that genes for ribosomal RNA are apparently shut off soon after the end of log-phase growth in wild-type cells but continue to be transcribed in cells of *rfr* 10 (unpublished work of C. Hussey, R. L. and A. L. S.). We plan to verify this hypothesis by testing whether vegetative polymerase, and not sporulation polymerase, will synthesize ribosomal RNA *in vitro* with *B. subtilis* DNA as a template.

We thank Professors S. E. Luria, J. L. Strominger, and P. Schaeffer for their interest and facilities. Rifampicin and rifamycin were the gifts of Ciba and Lepetit respectively. A. L. S. was a predoctoral fellow of the US National Institutes of Health and a postdoctoral fellow of the American Cancer Society. R. L. is a junior fellow of the Harvard Society of Fellows. This work was supported by a grant from the US National Science Foundation to R. L. and J. D. Watson and grants from the US National Institutes of Health and US National Science Foundation to S. E. Luria.

Structural Alteration of RNA Polymerase during Sporulation

by

RICHARD LOSICK

ROSALIND G. SHORENSTEIN

Harvard University

ABRAHAM L. SONENSHEIN

Department of Biology,
Massachusetts Institute of Technology,
and Institut de Microbiologie,
Faculté des Sciences,
91 Orsay

RNA polymerase from sporulating cells of *B. subtilis* has a subunit structure different from the vegetative enzyme. This alteration of RNA polymerase may be responsible for the turn-off of vegetative genes during spore formation.

THE kinds of enzyme activities and messenger RNA molecules found in sporulating cells of *Bacillus subtilis* are strikingly different from those found in vegetative cells¹⁻⁴. It is likely that these differences are brought about by the expression of new classes of genes during sporulation and the turn-off of certain vegetative genes, though little is known about the mechanism by which this change-over is controlled. Recently, Travers^{5,6} and Summers and Siegel⁷ have suggested that changes in the template specificity of RNA polymerase after phage infection are responsible for the expression of new phage genes and possibly the turn-off of host genes. In the case of coliphage T4, host RNA polymerase σ factor is replaced during infection by a new phage-induced σ factor, which directs the transcription of a different portion of the phage genome than does the σ factor of uninfected cells. We previously reported findings that suggested that a similar mechanism controls gene expression at the transcriptional level during bacterial sporulation⁸. Early in the process leading to sporulation, *B. subtilis* RNA polymerase changes dramatically in template specificity; it completely loses the ability to transcribe phage ϕ DNA, a finding consistent with the known inability to grow or produce phage specific antigens in sporulating cells. In the preceding article⁹, we provide evidence that this change is critical for sporulation because mutants that alter the RNA polymerase in such a way that it retains the ability to transcribe phage ϕ DNA also cause failure to sporulate. The loss of "vegetative" template specificity may be responsible for the turn-off of vegetative genes during spore formation.

Here we report that during sporulation the core of RNA polymerase undergoes an alteration which may be responsible for the loss of vegetative template specificity. We have reversibly fractionated vegetative RNA polymerase into a 57,000 molecular weight σ factor and a core enzyme by phosphocellulose chromatography. The core enzyme transcribes the synthetic template poly dAT but not ϕ DNA; transcription of the phage DNA is restored by addition of σ factor to the vegetative core. Phosphocellulose enzyme from sporulating cells contains an altered β subunit and does not transcribe ϕ DNA even after addition of σ factor from vegetative RNA polymerase. The failure of sporulation phosphocellulose enzyme to complement vegetative σ factor may be responsible for the loss of vegetative template specificity.

Transcription of ϕ DNA requires a σ Factor

RNA polymerase was purified from vegetative cells of *B. subtilis* strain 3610 by ammonium sulphate fractionation, DEAE-cellulose column chromatography, DNA-cellulose chromatography and zone centrifugation. After sedimentation through a glycerol gradient, RNA polymerase activity coincides with a protein peak; the enzyme is therefore highly purified. Purified enzyme transcribes both phage ϕ DNA and poly dAT (Table 1). The purified polymerase was then applied to a phosphocellulose column and eluted between 0.25 and 0.4 M KCl. This procedure is known to release a factor needed for the transcription

of phage T4 DNA from *E. coli* RNA polymerase¹². After phosphocellulose chromatography, the vegetative RNA polymerase fails to transcribe phage ϕ DNA, although it is even more active than the intact enzyme with poly dAT as a template (Table 1). Zone centrifugation showed that phosphocellulose enzyme has a sedimentation coefficient of 13.5 S compared with 15.4 S for RNA polymerase before the phosphocellulose step (Fig. 1).

These results suggest that phosphocellulose chromatography removes from vegetative polymerase a factor needed for the transcription of ϕ DNA, leaving a core enzyme which transcribes poly dAT. This factor can be found in the flow-through of the phosphocellulose column and will restore transcription of the phage DNA when added to vegetative core enzyme. Phosphocellulose flow-through was obtained from enzyme purified either through DEAE-cellulose or DNA-cellulose chromatography. Fig. 2 shows that the activity of RNA polymerase of the core fraction with ϕ DNA is stimulated several-fold by the addition of flow-through to vegetative core enzyme.

E. coli RNA polymerase can also transcribe ϕ DNA,

Fig. 1. Zone centrifugation of RNA polymerase. Samples containing, in 0.5 ml., 50 μ g of vegetative DNA-cellulose enzyme and 50 μ g of vegetative core enzyme were layered on parallel 12 ml. linear gradients of 10–30 per cent glycerol in buffer containing 0.01 M Tris-HCl (pH 7.9), 0.01 M MgCl₂, 0.0001 M EDTA, 0.0001 M dithiothreitol and 0.15 M KCl. Following centrifugation for 15 h at 40,000 r.p.m. in an International 'SB 283' rotor at 3° C, fractions (0.4 ml.) were collected and 0.025 ml. of each fraction was assayed as previously described⁸. Two molecular weight markers, haemoglobin (4.6 S) and β -galactosidase (16 S), were centrifuged on a parallel gradient.

Table 1. SPECIFIC ACTIVITY OF VEGETATIVE AND SPORULATION RNA POLYMERASE

Enzyme	Specific activity (units/mg protein)	
	ϕ e DNA	Poly dAT
Vegetative	198	77
Vegetative core	18	320
Sporulation	5	87
Sporulation core	6	250
Vegetative (2 μ g) and sporulation (9 μ g)	199	—

Vegetative cells were obtained by growing *B. subtilis* 3610 in medium 121B¹⁴ and harvesting during mid-log phase. Cells were disrupted by sonication and vegetative RNA polymerase purified by high speed centrifugation, ammonium sulphate fractionation and DEAE-cellulose column chromatography as previously described⁴. After the ammonium sulphate step, a volume equal to 5 per cent of the volume of the extract of a phenylmethane-sulphonyl fluoride solution (6 mg/ml of ethanol) was added to inhibit proteases. The vegetative enzyme was further purified by calf-thymus DNA-cellulose column chromatography using stepwise elution with 0.15–0.6 M KCl according to the method of Alberts *et al.*¹¹. Finally, the enzyme was sedimented through a 10–30 per cent glycerol gradient containing 0.15 M KCl. Vegetative core enzyme was obtained by applying glycerol gradient enzyme to a phosphocellulose column and eluting stepwise between 0.25 and 0.4 M KCl¹². Sporulating cells were also grown in 121B¹⁰ medium and harvested 6 h after the end of logarithmic growth. Cells were disrupted by sonication and sporulation enzyme purified by high speed centrifugation and ammonium sulphate fractionation⁴. The enzyme was next applied to a DEAE-cellulose column and eluted with a 0.1 to 0.3 M KCl gradient. The enzyme was further purified by glycerol density centrifugation. Sporulation core enzyme was obtained by phosphocellulose chromatography of the DEAE-cellulose enzyme as described in the legend to Fig. 5. Enzymes were assayed with either ϕ e DNA or poly dAT as previously described⁴. One unit of specific activity is that amount of enzyme which incorporated 1 nmole of ¹⁴C-AMP in 10 min.

and it seemed possible that *E. coli* σ factor would enable *B. subtilis* core enzyme to transcribe the phage DNA. Fig. 2 shows that, in fact, *E. coli* σ factor greatly stimulates vegetative *B. subtilis* core enzyme with ϕ e DNA as a template. We conclude that vegetative *B. subtilis* RNA polymerase consists of a core enzyme plus a σ factor necessary for the transcription of ϕ e DNA. The factor is sufficiently similar to the *E. coli* σ factor to allow the latter to complement *B. subtilis* core enzyme. Kerjan and Szulmajster have also released a factor from *B. subtilis* polymerase by phosphocellulose chromatography¹³.

Polypeptide Composition of Vegetative RNA Polymerase

The subunit structure of vegetative RNA polymerase was analysed by sodium dodecyl sulphate (SDS) polyacrylamide gel electrophoresis, which separates polypeptides on the basis of molecular weight. Fig. 3 shows the gel pattern for vegetative enzyme and vegetative core enzyme. Vegetative enzyme preparations contain polypeptides of 155,000, 120,000, 57,000 and 45,000 daltons. In gels of phosphocellulose enzyme, the 57,000 dalton

Fig. 2. Stimulation of core enzyme by σ factor. *B. subtilis* σ factor was obtained by phosphocellulose chromatography of vegetative enzyme purified either only through the DEAE-cellulose step (○) or through the DNA-cellulose step (●). Varying amounts of flow-through from the phosphocellulose chromatography were added to 3 μ g of vegetative core enzyme or 4 μ g of sporulation core enzyme and assayed as previously described with ϕ e DNA as a template⁴. In the case of σ factor derived from DEAE-cellulose enzyme, a background value of 7 c.p.m./ μ g of flow-through has been subtracted because of transcription of ϕ e DNA in the absence of added core enzyme. A value of 39 c.p.m./ μ g of flow-through has been subtracted in the case of σ factor derived from DNA-cellulose enzyme. This background incorporation is the result of small amounts of core enzyme present in the phosphocellulose flow-through. *E. coli* σ factor was the gift of R. R. Burgess and was assayed in the presence of 3 μ g of vegetative core or 4 μ g of sporulation core. A background value of 11 c.p.m./ μ g of σ factor was subtracted.

Fig. 3. SDS polyacrylamide gel electrophoresis patterns of vegetative and sporulation RNA polymerase. From left to right: vegetative core (A); vegetative glycerol gradient enzyme (B); sporulation core (C). Samples were carboxymethylated according to the method of Pringle¹⁴ before electrophoresis. Carboxymethylation destroys proteases which may be present in trace amounts and are resistant to SDS and attack other proteins during denaturation in SDS¹⁴. Gels containing 0.1 per cent SDS and 5 per cent acrylamide were run for 3 h at 8 mA per gel according to the procedure of Weber and Osborn¹⁵. The gels were then stained with Coomassie brilliant blue and destained electrophoretically according to Weber and Osborn¹⁵.

subunit is the only one missing. It is found, instead, in gels of the flow-through of phosphocellulose chromatography. The 57,000 dalton subunit therefore seems to be the σ factor of vegetative RNA polymerase. Avila *et al.*¹⁵ have reported a similar molecular weight for the *B. subtilis* σ factor. In view of our finding that both *B. subtilis* and *E. coli* factors complement *B. subtilis* core enzyme, it is interesting to note that the factor of *B. subtilis* is considerably smaller than the *E. coli* factor (95,000 daltons¹²).

Electrophoresis for extended times resolves the 155,000 dalton band into two polypeptides (Fig. 4) which probably correspond to the β and β' polypeptides of *E. coli* RNA polymerase (about 160,000 daltons¹⁶). The 45,000 dalton band presumably represents the α polypeptide (40,000 daltons in *E. coli*¹⁶). The molar ratio of the 45,000 and 155,000 dalton bands calculated from densitometer tracings is 1:1.1, which is in good agreement with the $\alpha_2\beta\beta'$ structure of *E. coli* RNA polymerase¹⁶. The 120,000 dalton polypeptide is probably a contaminating protein; it is present in variable amounts in different preparations and is absent in at least some preparations that are active with both poly dAT and ϕ e DNA. It seems therefore that vegetative RNA polymerase from *B. subtilis* has a subunit composition similar to that of the *E. coli* enzyme consisting of α , β , β' and σ polypeptides.

Vegetative σ Factor does not complement Sporulation Core Enzyme

Sporulation RNA polymerase was partially purified by ammonium sulphate fractionation, DEAE-cellulose column chromatography and zone centrifugation. Polymerase activity was found to coincide with a protein shoulder after sedimentation through a glycerol density gradient. Chromatography on calf thymus DNA-cellulose was not used because it was found that sporulation polymerase binds poorly to such a column. Table 1 shows that the sporulation enzyme fails to transcribe ϕ e DNA even though it is active with poly dAT as a template. Failure to transcribe the phage DNA is an inherent property of sporula-

Fig. 4. Separation of β and β' by polyacrylamide gel electrophoresis for extended time. Vegetative enzyme (V); sporulation enzyme (S). SDS gels were run as described in the legend to Fig. 3, except that electrophoresis was for 8 h. Only the 155,000 dalton bands are shown.

tion RNA polymerase and not the result of a specific antagonist of ϕ e DNA transcription, for there is no inhibition of transcription of ϕ e DNA when sporulation enzyme is added to vegetative enzyme (Table 1).

Sporulation enzyme purified through the DEAE-cellulose step was applied to a phosphocellulose column. The flow-through of the column did not stimulate transcription of ϕ e DNA by vegetative core enzyme. Thus if sporulation enzyme contained vegetative σ factor, this factor is not released by phosphocellulose chromatography. Sporulation enzyme was eluted from the column with a linear KCl gradient. Fig. 5 shows that enzyme activity corresponded to a protein peak, so that the enzyme is highly purified. We shall provisionally call the activity purified by phosphocellulose sporulation "core" enzyme. Fig. 2 shows that sporulation core enzyme does not transcribe phage ϕ e DNA even after addition of σ factor derived from either vegetative *B. subtilis* polymerase or from *E. coli* polymerase.

Sporulation RNA Polymerase contains an Altered β Polypeptide

Sporulation core enzyme contains polypeptides of 155,000 and 45,000 daltons and small amounts on a molar basis of a 120,000 molecular weight species (Fig. 3). These polypeptides are similar in molecular weight to corresponding polypeptides of vegetative core enzyme. In addition, there is in the sporulation core enzyme a polypeptide of 110,000 molecular weight. The following evidence indicates that this new polypeptide is present in place of one of the β polypeptides. (a) The 155,000 dalton band of sporulation enzyme does not separate into two polypeptides after extended electrophoresis as does the vegetative β band (Fig. 4). (b) The molar ratio of the 45,000 dalton band to the 110,000 and the 155,000 dalton polypeptides is 1:0.54:0.47. Thus there is approximately only half as much of the 155,000 subunit species in the sporulation enzyme as in the vegetative enzyme. These findings suggest that one of the 155,000 dalton polypeptides is missing and is replaced in sporulation polymerase by a new subunit of 110,000 molecular weight. Sporulation core also contains small amounts of material of about 60,000 daltons. We cannot therefore conclude that sporulation core enzyme is entirely free of either vegetative or sporulation σ factors.

To test the possibility that the structural alteration of RNA polymerase takes place *in vitro* during purification rather than *in vivo* during sporulation, 6 g of vegetative cells was mixed with 18 g of sporulating cells. The mixture was sonicated and RNA polymerase was partially purified by ammonium sulphate fractionation. Next, vegetative enzyme was separated from sporulation enzyme by taking advantage of the observation mentioned

here that sporulation RNA polymerase binds poorly to a calf-thymus DNA-cellulose column. Vegetative RNA polymerase, eluted from the DNA-cellulose column and sedimented through a glycerol density gradient, was still active with ϕ e DNA as a template, and on SDS gel analysis revealed the same subunit structure as vegetative enzyme. This result argues that structural alteration of sporulation RNA polymerase takes place *in vivo* and is not the result of proteolysis during purification.

Conclusions

In an earlier publication⁸ we showed that RNA polymerase loses the ability to transcribe ϕ e DNA early during sporulation. Here we show that the vegetative enzyme depends on a σ factor of 57,000 molecular weight of the transcription of ϕ e DNA. Sporulation polymerase that has been purified by phosphocellulose chromatography will not transcribe ϕ e DNA even when the σ factor from vegetative enzyme is supplied. One possibility is that sporulation polymerase contains a sporulation σ factor that is not released by phosphocellulose chromatography and that this sporulation σ factor prevents complementation by vegetative σ factor. An attractive possibility, not incompatible with the above hypothesis, is that RNA polymerase core is changed in such a way that it cannot complement vegetative σ factor. This might account for the loss of vegetative template specificity during sporulation. It should be noted, however, that this need not be the only mechanism, for inactivation of σ early during sporulation would also prevent the transcription of ϕ e DNA.

Analysis of subunit structure by SDS gel electrophoresis has revealed a difference between vegetative and sporulation RNA polymerase cores. Vegetative RNA polymerase contains two β polypeptides of about 155,000 molecular weight. In the sporulation RNA polymerase one of these polypeptides is only 110,000 daltons. This feature of the sporulation core enzyme may be the modification responsible for its failure to complement vegetative RNA polymerase σ factor. It is interesting to note that after phage T4

Fig. 5. Phosphocellulose chromatography of sporulation RNA polymerase. Phosphocellulose (Whatman 'P11', 7.4 mequiv/g) was washed with acid and base and titrated to pH 7.9 according to the method of Burgess *et al.*¹². This material was used for a 30 ml. column and equilibrated extensively with buffer containing 0.05 M Tris-HCl (pH 7.9 at 25°C), 0.1 M KCl, 0.0001 M EDTA, 0.0001 M dithiothreitol and 20 per cent glycerol. A sample containing 78 mg of sporulation RNA polymerase purified through the DEAE-cellulose step in 24 ml. of the above buffer containing 0.12 M KCl was applied to the column over the course of 1 h. The column was washed with buffer containing 0.15 M KCl and then 0.25 M KCl and then eluted with a 100 ml. gradient from 0.2 M to 0.8 M KCl. 4 ml. fractions were collected.

infection of *E. coli*, both the α polypeptide¹⁷ and the β' polypeptide (personal communication of A. A. Travers) have altered electrophoretic properties and that *E. coli* σ factor does not stimulate this core polymerase from infected cells to the same extent that it stimulates core enzyme from uninfected cells (personal communication of C. Goff and A. A. Travers).

The 110,000 dalton polypeptide of sporulation RNA polymerase may be derived from one of the β polypeptides by specific proteolytic cleavage. Sadoff and Celikkol¹⁸ have shown that fructose-1,6-diphosphate aldolase is modified by such a proteolytic step during sporulation of *B. cereus*. It is not yet excluded that the 110,000 dalton polypeptide is synthesized specifically during sporulation and replaces one of the β polypeptides. In phage T4 infection, the alteration of the α polypeptide is the result of modification of the α subunit of uninfected cells rather than replacement by a new polypeptide (personal communication of C. Goff and K. Weber).

The preceding article describes a class of rifampicin-resistant mutants of *B. subtilis* which, as a result of a single mutational event, fail to sporulate and retain the ability to transcribe phage ϕ DNA. These mutants provide direct evidence that the change in the template specificity of RNA polymerase is essential for sporulation. Our present finding of an alteration of a β polypeptide of RNA polymerase during sporulation suggests an explanation for the inability of the polymerase of the rifampicin-resistant mutants to undergo change in template specificity. Rifampicin is a specific inhibitor of RNA polymerase core and RNA polymerase from at least one *E. coli* rifampicin-resistant mutant contains an altered β polypeptide¹⁹. Mutation to rifampicin resistance in *B. subtilis* may modify a β polypeptide in such a way as to make it resistant to specific proteolytic cleavage. Thus the non-sporulating, rifampicin-resistant mutants of *B. subtilis* may retain the ability to transcribe ϕ DNA during stationary phase because the RNA polymerase core enzyme remains unmodified.

There is reason to believe that at least some vegetative genes are turned off during sporulation. Various enzyme activities and species of messenger RNA found in vegetative cells are not present in sporulating cells^{1,3,4}. In

addition, the synthesis of ribosomal RNA is arrested during sporulation (unpublished results of C. Hussey, R. L. and A. L. S.). Assuming that the vegetative RNA polymerase σ factor which we have described directs the transcription of these vegetative genes, the molecular event responsible for the turn-off of vegetative genes might be a structural alteration of RNA polymerase. Many new genes are almost certainly transcribed during sporulation. This transcription may be directed by specific sporulation factors. We are now searching for such factors.

We thank K. Weber, A. A. Travers, J. L. Strominger, S. E. Luria, C. Hussey and J. Pero for helpful discussions. R. L. is a junior fellow of the Harvard Society of Fellows, R. G. S. is a predoctoral fellow of the US National Science Foundation, and A. L. S. was a postdoctoral fellow of the American Cancer Society and a predoctoral fellow of the US National Institutes of Health. This work was supported by a US National Science Foundation grant to R. L. and J. D. Watson, and grants from the US National Institutes of Health and US National Science Foundation to S. E. Luria.

The synthesis of haemoglobin in a cell free system containing yeast tRNA is initiated by a specific methionine tRNA. Another methionine tRNA responds to internal codons in the messenger. The initiating methionine is removed from the nascent protein to leave valine as the terminal amino-acid, but cannot be removed when its amino group is blocked as in formylmethionine.

BACTERIA contain two major species of methionine tRNA, tRNA^{Met} and tRNA^{Met}_f (refs. 1, 2). The latter can be enzymatically formylated to fMet-tRNA^{Met}_f (ref. 3) and is used to initiate protein synthesis. tRNA^{Met} inserts its methionine only at internal positions of a polypeptide chain. The presence of fMet-tRNA^{Met}_f in mitochondria^{4,5} and in chloroplasts⁶ suggests that this tRNA is involved in the initiation of protein synthesis in these organelles

too. By contrast, the cytoplasm of eukaryotic cells does not contain a formylated methionyl-tRNA^{Met}_f.

Two species of methionine tRNA are present, however, in the cytoplasm of several eukaryotic cells, including guinea-pig liver⁷, rat liver⁸, yeast^{9,10} and wheat germ¹¹. When added to a bacterial cell-free protein synthesizing system, one of these, tRNA^{Met}_M, behaves similarly to *Escherichia coli* tRNA^{Met} and inserts methionine into the internal position of a polypeptide chain. The other, tRNA^{Met}_F, is not formylated *in vivo*, but can be formylated *in vitro* by *E. coli* transformylase. The yeast fMet-tRNA^{Met}_F thus formed initiates protein synthesis in extracts of *E. coli* with the same specific requirements and conditions as does *E. coli* fMet-tRNA^{Met}_f (refs. 9, 10).

Abbreviations used: tRNA^{Met}_f, the bacterial methionine tRNA which is formylated *in vivo*; tRNA^{Met}_M, the bacterial methionine tRNA which is not formylated *in vivo*; tRNA^{Met}_F, the yeast methionine tRNA which is not formylated *in vivo*, but which can be formylated by bacterial transformylase; tRNA^{Met}_M, the yeast methionine tRNA which is not formylated *in vitro* or *in vivo*. (The latter two designations do not represent definitive usage.—Editor.)

Fig. 1. Kinetics of amino-acid incorporation into protein. Data for formyl- ^{35}S -Met-tRNA $^{\text{MetF}}$ are plotted twice, on different scales, to show the relationships with the other two Met-tRNAs. O, Formyl- ^{35}S -Met-tRNA $^{\text{MetF}}$; \bullet , ^{35}S -Met-tRNA $^{\text{MetM}}$; \times , ^{35}S -Met-tRNA $^{\text{MetE}}$. All reactions contained (per ml.) 0.62 ml. reticulocyte lysate, 0.92 μmoles ATP, 0.19 μmoles GTP, 50 μmoles KCl, 5 μmoles mercaptoethanol, 11 μmoles creatine phosphate, 1 mg creatine phosphokinase, 25 μmoles HEPES (pH 7.0), 3.1 μmoles magnesium acetate, 34 μg haemin, 0.1 μmoles of all twenty amino-acids (non-radioactive), except non-radioactive methionine (1.2 μmoles). Where indicated, reactions contained (per ml.) 8×10^5 c.p.m. formyl- ^{35}S -methionyl-tRNA $^{\text{MetF}}$ (48,000 c.p.m./ μg tRNA; specific activity of ^{35}S -methionine, 5,000 mCi/mmol; 20 per cent counting efficiency), 5×10^5 c.p.m. ^{35}S -Met-tRNA $^{\text{MetM}}$ (30,000 c.p.m./ μg) or 8×10^5 c.p.m. ^{35}S -Met-tRNA $^{\text{MetE}}$ (about 4,000 c.p.m./ μg). Incubation was at 25°C ; at indicated times 15 μl . aliquots were taken into 0.5 ml. cold water. KOH was added to 0.1 M; after incubation at 37°C for 10 min, trichloroacetic acid (TCA) was added to 5 per cent. The precipitate was collected on fibreglass filters, washed with 5 per cent TCA, dried, and counted on an end window counter at about 20 per cent efficiency. Methionine transfer RNA, tRNA $^{\text{MetF}}$ and tRNA $^{\text{MetM}}$ were purified from yeast as described previously¹⁰; the former was at least 90 per cent pure, the latter 10 per cent. Neither preparation was contaminated with the other methionine tRNA species. Charging and formylation by the *E. coli* enzymes was also described previously¹⁰. To prepare the reticulocyte extracts¹⁸, New Zealand white rabbits, weighing 5 to 7 lb., were made anaemic by subcutaneous injection of 2.5 per cent phenylhydrazine solution according to the following schedule: 1.0 ml. on day 1, 0.8 ml. on day 2, 0.6 ml. on day 3, 0.8 ml. on day 4, 1.0 ml. on day 5. On the seventh day about 30 ml. of blood taken from the ear was collected into 30 ml. of buffer A (140 mM NaCl, 1.5 mM magnesium acetate, 5 mM KCl, 0.001 per cent heparin). After centrifugation, the reticulocytes were washed by centrifugation three times in buffer A without heparin. The packed reticulocytes were lysed by addition of 1 volume cold water; after centrifugation at 15,000 r.p.m. for 20 min in the 'Sorvall SS34' rotor, the lysate was stored frozen in small aliquots at -80°C .

Furthermore, yeast Met-tRNA $^{\text{MetF}}$ and *E. coli* Met-tRNA $^{\text{MetE}}$ are unable to insert methionine into the internal positions of a polypeptide in either *E. coli*¹² or in yeast (unpublished results of D. H., U. L. R. and H. F. L.) protein synthesizing systems.

The analogous properties of the yeast tRNA $^{\text{MetF}}$ and *E. coli* tRNA $^{\text{MetE}}$ suggest that this species might initiate the synthesis of eukaryotic proteins. We show now that haemoglobin synthesis in a cell-free system is initiated by Met-tRNA $^{\text{MetF}}$ and that the amino terminal methionine is enzymatically removed from the nascent product. If the methionine amino group is blocked by a formyl (or acetyl) group, the amino terminal methionine is not removed. By contrast, tRNA $^{\text{MetM}}$ donates its methionine only into the internal positions of the α and β chains.

Our results confirm the fundamental finding of Wilson and Dintzis¹³ that nascent α -haemoglobin polypeptides in intact reticulocytes contain methionine at their amino termini, and that the methionine residue is subsequently removed. Using synthetic polyribonucleotides as messenger and ribosomes from rabbit reticulocytes and ascites tumour cells, respectively, Gupta *et al.*¹⁴ and Smith, Marcker and Brown^{15,16} showed that methionine incorporated from Met-tRNA $^{\text{MetM}}$ (designated Met-tRNA $^{\text{M}}$ in refs. 15, 16) is found exclusively in internal positions of polypeptide chains, while that from Met-tRNA $^{\text{MetF}}$ (Met-tRNA $^{\text{F}}$ in refs. 15, 16) is found only amino terminal.

In cell-free extracts of rabbit reticulocytes more than 90 per cent of the protein produced is haemoglobin and the system initiates synthesis of new polypeptides^{19,20}. Fig. 1 shows that ^{35}S -methionine from yeast ^{35}S -Met-tRNA $^{\text{MetM}}$ is incorporated very efficiently into protein, whereas ^{35}S -Met-tRNA $^{\text{MetF}}$ seems to be poorly incorporated. Two other groups have made similar observations^{14,21}. When the methionine on tRNA $^{\text{MetF}}$ is formylated (fMet-tRNA $^{\text{MetF}}$), however, methionine radioactivity

Fig. 2. Analysis of ^{35}S -Met-tRNA $^{\text{MetM}}$ product. A 0.1 ml. reaction mixture, containing ^{35}S -Met-tRNA $^{\text{MetM}}$ (Fig. 1), was incubated at 37°C for 10 min (11,400 c.p.m. was incorporated). Pancreatic ribonuclease (to 100 $\mu\text{g}/\text{ml}$) and EDTA (to 0.03 M) were added and incubation continued for 10 min. The sample was precipitated with trichloroacetic acid, centrifuged, and the precipitate washed by centrifugation three times with 5 per cent TCA. A small amount of water was added and the precipitate lyophilized until the solution was no longer acid. The precipitate was resuspended at 10 mg/ml. in 1 per cent NH_4HCO_3 containing trypsin (TPCK, Worthington) at 0.2 mg/ml. After incubation at 37°C for 4 h, the material was freeze-dried, and subjected to paper ionophoresis at pH 3.5 for 3 h at 45 V/cm. 1 cm strips were cut out and radioactivity was counted in a scintillation counter using a toluene-based scintillator; the strips were then washed in fresh toluene, dried, and stained for methionine as described in ref. 29. The spot indicated by the dotted line (29 cm) was considerably fainter than the other two. Free methionine would be at 12 cm.

Table 1. EFFECT OF ANTIBIOTICS ON PROTEIN SYNTHESIS

Addition	Formyl- ^{35}S -methionyl-tRNA $^{\text{MetF}}$	^{35}S -Methionyl-tRNA $^{\text{MetM}}$	^{35}S -Methionyl-tRNA $^{\text{MetE}}$
None	1.00 (1,466 c.p.m.)	1.00 (136 c.p.m.)	1.00 (4,017 c.p.m.)
Chloramphenicol (100 $\mu\text{g}/\text{ml}$.)	0.98	1.16	0.90
Cycloheximide (200 $\mu\text{g}/\text{ml}$.)	0.00	0.01	0.00
Aurintricarboxylate (10^{-4} M)	0.01	0.02	0.31

Reactions are described in the legend to Fig. 1; 15 μl . aliquots were counted after 10 min incubation at 37°C ; zero time backgrounds (8–12 c.p.m.) have been subtracted.

is transferred into protein almost as efficiently as from Met-tRNA^{Met}. Because proteins are synthesized from the amino terminus, incorporation of a formylmethionyl residue must represent initiation of new polypeptide chains.

Table 1 presents evidence that protein synthesis is occurring solely on cytoplasmic ribosomes. Incorporation by all three ³⁵S-Met-tRNAs is completely blocked by cycloheximide, an antibiotic which specifically inhibits synthesis by cytoplasmic (80S) ribosomes, but is without effect on bacterial and mitochondrial ribosomes. Aurintricarboxylate (ATA), a specific inhibitor of polypeptide chain initiation³⁵, completely blocks incorporation from ³⁵S-Met-tRNA^{Met} and its formylated derivative.

Incorporation by Met-tRNA^{Met}

Fig. 2 shows that tRNA^{Met} transfers methionine exclusively into internal positions of both the α and β chains. Protein synthesized *in vitro* and labelled with ³⁵S-Met-tRNA^{Met} was digested with trypsin and analysed by paper ionophoresis at pH 3.5 (Fig. 2). The three radioactive peptides observed had mobilities identical to the three methionine-containing peptides from authentic rabbit haemoglobin. Similar results (unpublished) were obtained by ionophoresis at pH 4.5. Peptides A and C are most likely the single methionine-containing tryptic peptides from the α and β chain, respectively^{22,23}, whereas B is most likely a derivative of C resulting from chymotrypsin impurities in the trypsin.

Incorporation by fMet-tRNA^{Met}

Several experiments show that formylmethionine residues from fMet-tRNA^{Met} are incorporated into the amino

Fig. 3. Pronase digestion of formyl-³⁵S-methionyl product. Protein synthesized *in vitro* (10 min at 37°C, Fig. 1) containing formyl ³⁵S-Met-tRNA^{Met} was isolated as in Fig. 2, and digested with pronase³⁰ (Calbiochem B grade, 0.2 mg/ml.). A small amount of formyl-methionyl-valine was added and the product was analysed by paper ionophoresis at pH 3.5 and 4.5 fMet-Val and other markers were detected as in Fig. 2. The large peak of free methionine (1,100 c.p.m.) results from enzymic deformation of formylmethionine peptides by the pronase preparation. In the same conditions digestion of the bacteriophage f2 coat protein and RNA polymerase, synthesized *in vitro* and containing an amino terminal formyl-³⁵S-methionine residue³⁰, also yielded a large amount of radioactive methionine in addition to the formyl-³⁵S-methionyl amino-acids³⁰.

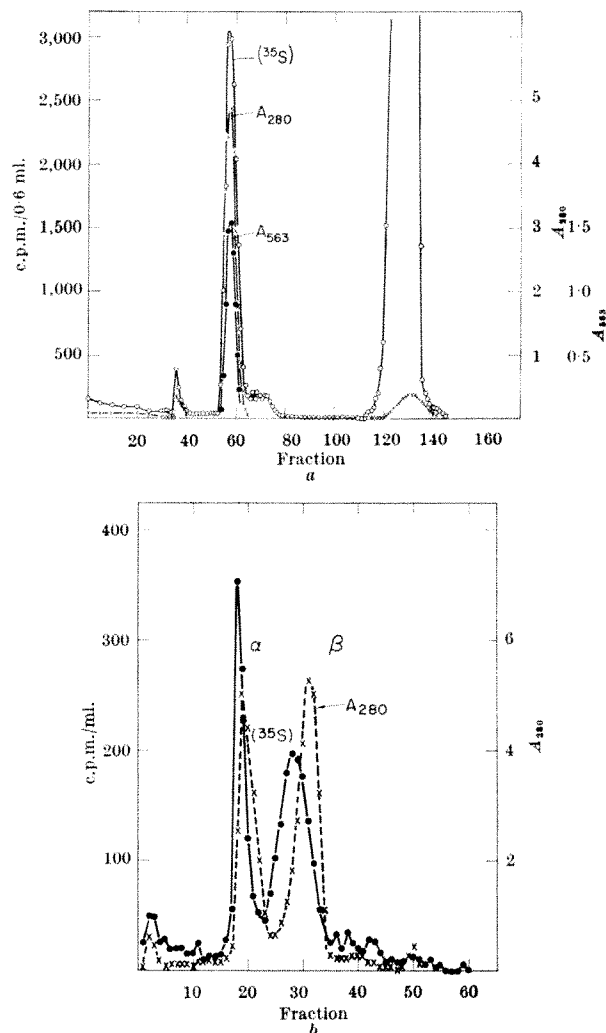

Fig. 4. Chromatography of formyl-³⁵S-methionyl reaction product. *a*, Sephadex G-75: ○, ³⁵S; ×, A₂₈₀ nm; ●, A₅₆₃ nm. *b*, Isolated globin chains on CM-cellulose: ●, ³⁵S; ×, A₂₈₀ nm. In (*a*), a 2.0 ml. *in vitro* reaction labelled with formyl-³⁵S-methionyl-tRNA^{Met} (Fig. 1; 20 min incubation at 25°C; total of about 220,000 c.p.m. protein) was treated with ribonuclease (Fig. 2), then chromatographed on a column (8.4 × 147 cm) of Sephadex G-75 equilibrated with 0.1 M NaCl-0.01 M Tris (pH 7.6)-0.001 M KCN. The same buffer was used for elution and 10 ml. fractions were collected. Haemoglobin, as measured by the haem absorbance at 563 nm, elutes in fractions 53-60; the large peak of radioactivity eluting between fractions 115 and 140 is low molecular weight material derived from the added tRNA; totally excluded material (dextran blue test) elutes at fraction 35. In (*b*), a 0.1 ml. reaction containing formyl-³⁵S-methionyl-tRNA^{Met} (Fig. 1) was stopped by chilling, and globin was prepared by precipitation with acid acetone (ref. 31); 50 mg purified rabbit globin was added, and the mixture was chromatographed on a column (0.9 × 23 cm) of CM-cellulose (Whatman CM32). Elution was performed as in ref. 32, except that all buffers contained 0.001 M 2-mercaptoethanol. 6 ml. fractions were collected; 1 ml. fractions were mixed with a dioxane-based scintillation fluid and counted in the scintillation counter.

terminus of haemoglobin. First, protein synthesized *in vitro* and labelled with N-formyl ³⁵S-methionyl-tRNA^{Met} was digested with pronase, and the products were analysed by paper ionophoresis at pH 3.5 and 4.5 (Fig. 3). Peak A was inseparable from the marker formylmethionyl-valine. Except formylmethionyl-asparagine and formylmethionyl-glutamine, which were not tested, all other N-formylmethionyl amino-acids were separable from peak A and formylmethionyl-valine at at least one pH (unpublished results of H. F. L.). Peptides B and C migrated more slowly than N-formylmethionyl-leucine, the slowest moving formylmethionyl dipeptide, and are therefore probably tri or tetrapeptides. Because valine is at the amino terminus of both the α and β chains of rabbit haemoglobin, these results suggest that at least one of the synthesized polypeptides is a haemoglobin chain beginning with the sequence fMet-Val. . .

Fig. 5. Trypsin digest of formyl- ^{35}S -methionine-labelled α and β chains. Purified α and β chains labelled with formyl- ^{35}S -methionine, and also the total reaction product (Fig. 4) were digested with trypsin and analysed as in Fig. 2. The radioactivity at the origin in the peak α sample is undigested material.

Second, a reaction mixture containing formyl- ^{35}S -methionyl-tRNA^{MetF} was chromatographed on a column of 'Sephadex G-75'. Virtually all of the incorporated radioactivity chromatographed identically to the intact $\alpha_2\beta_2$ haemoglobin, measured by absorbance at 563 nm, present in the reticulocyte extract (Fig. 4a). This experiment suggests that formylmethionine is incorporated into intact, functional α and β chains and we confirmed this by the experiment in Fig. 4b. Globin chains were prepared from a similar *in vitro* reaction, and separated on a column of carboxymethyl (CM) cellulose. Two peaks of radioactivity were found; they eluted from the column slightly before the authentic α and β chain markers. CM-cellulose separates largely according to protein charge, so that this result is accounted for by incorporation of the formyl- ^{35}S -methionine radioactivity into α and β chains with a reduced positive charge, because of the blocked N-terminal amino group.

Finally, when digested with trypsin, the formyl- ^{35}S -methionine-labelled α and β chains each yielded a single radioactive peptide (Fig. 5). These have the expected ionophoretic mobility of the amino-terminal tryptic peptides of α and β chains containing an N-terminal formylmethionine. When these peptides were treated with dilute HCl to remove the formyl residue, they had an ionophoretic mobility consistent with the acquisition of a single positive charge (Fig. 6, top panel). Further characterization of these peptides is in progress, but we suggest that a formylmethionine residue can be incorporated at the amino terminus of both α and β chains, and that no other polypeptide beginning with formylmethionine is produced in our system.

Incorporation by Met-tRNA^{MetF}

The low level of methionine incorporation from ^{35}S -Met-tRNA^{MetF} (Fig. 1) could be explained by any of the following hypotheses: (1) Met-tRNA^{MetF}, like fMet-tRNA^{MetF}, is actually used for the initiation of haemoglobin synthesis, but the amino terminal methionine is rapidly removed from the nascent chain; (2) Met-tRNA^{MetF} is used for initiation of a protein synthesized in relatively small amounts, and (3) Met-tRNA^{MetF} inserts methionine into the internal positions of haemoglobin, but only poorly.

Evidence that both Met-tRNA^{MetF} and fMet-tRNA^{MetF} incorporate, respectively, methionine and formylmethionine into the same position of the polypeptide chain is derived from the experiment in Fig. 6. Protein synthe-

sized *in vitro* and labelled with ^{35}S -Met-tRNA^{MetF} was digested with trypsin and the product analysed by ionophoresis (middle panel). Two principal radioactive peptides were present and these had mobilities identical to those of the corresponding peptides from the product labelled with fMet-tRNA^{MetF} and from which the formyl groups had been removed by acid hydrolysis. Because no radioactive peptide having the mobility of the ^{35}S -Met-tRNA^{MetM} product—the internal methionine peptides of haemoglobin—was observed, we can also conclude that Met-tRNA^{MetF} probably transfers methionine only to the amino terminus of haemoglobin.

Table 2. SOURCE OF RADIOACTIVITY

	Formyl- ^{35}S -Met-tRNA ^{MetF} (106 $\mu\text{g}/\text{ml.}$)	^{35}S -Met-tRNA ^{MetF} (100 $\mu\text{g}/\text{ml.}$)	^{14}C -Lysine (1,162 c.p.m.)
No additions	1.00 (1,143 c.p.m.)	1.00 (82 c.p.m.)	1.00 (1,162 c.p.m.)
Plus fMet-tRNA ^{MetF} (76 $\mu\text{g}/\text{ml.}$)	Not done	0.25	0.81
Plus Met-tRNA ^{MetF} (76 $\mu\text{g}/\text{ml.}$)	0.19	0.23	0.79

Reactions are described in the legend to Fig. 1, except that those with ^{14}C -lysine contained no non-radioactive lysine, and 4 $\mu\text{Ci}/\text{ml.}$ ^{14}C -lysine (246 $\mu\text{Ci}/\text{mmole}$) and ^{35}S -methionyl-tRNA were added at 20 $\mu\text{g}/\text{ml.}$ Incubation was at 37° C for 10 min.

The experiment described in Table 2 also strongly indicates that Met-tRNA^{MetF} and fMet-tRNA^{MetF} compete for the same function—the initiation of haemoglobin synthesis. Thus (1) addition of Met-tRNA^{MetF} inhibits incorporation by formyl- ^{35}S -Met-tRNA^{MetF} and conversely non-radioactive fMet-tRNA^{MetF} inhibits incorporation by ^{35}S -Met-tRNA^{MetF}; and (2) the inhibition was specific, because the net level of haemoglobin synthesis—measured by incorporation of ^{14}C -lysine (Table 2) or ^{35}S -Met-tRNA^{MetM} (unpublished)—was not appreciably affected by either tRNA.

Furthermore, the low level of incorporation observed with ^{35}S -Met-tRNA^{MetF} as compared with formyl- ^{35}S -Met-tRNA^{MetF} suggests that ^{35}S -methionine incorporated from ^{35}S -Met-tRNA^{MetF} is removed from the nascent chain, whereas the formyl- ^{35}S -methionyl product is stable. A direct prediction of this is the conversion of a large amount of radioactivity from ^{35}S -Met-tRNA^{MetF} to free methionine.

Fig. 6. Analysis of ^{35}S -Met-tRNA^{MetF} product. (a) Formyl- ^{35}S -methionyl-tRNA^{MetF} + HCl; (b) ^{35}S -methionyl-tRNA^{MetF}; (c) ^{35}S -methionyl-tRNA^{MetM}. Reactions containing ^{35}S -Met-tRNA^{MetF} (Fig. 1, 2.5 min at 25° C) or ^{35}S -Met-tRNA^{MetM} (10 min at 25° C) were digested and analysed as in Fig. 5, except the tRNA^{MetF} reaction was stopped by alkali (0.1 M KOH, 37° C, 10 min) and no ribonuclease was added. Protein labelled *in vitro* with formyl- ^{35}S -methionyl-tRNA^{MetF} and digested with trypsin was treated with HCl (0.5 M, 90° C, 20 min)²² to remove the formyl residues. α and β indicate the positions of the formylmethionine peptides from the α and β chains (Fig. 5); A and B are the deacylated derivatives, respectively, of these peptides.

To test this, a small amount of ^{35}S -Met-tRNA^{MetF} was added to a reticulocyte cell-free system (Fig. 7). Results show, first, that within 3 min more than 60 per cent of the radioactivity was converted to acid soluble form. Paper ionophoresis at pH 1.9 revealed that all of the ^{35}S radioactivity solubilized is indeed ^{35}S -methionine. Second, this acid solubilization requires protein synthesis on cytoplasmic 80S ribosomes, for it is inhibited by cycloheximide or aurintricarboxylate, but not by chloramphenicol. Third, this acid solubilization is specific, for in similar experiments with ^{35}S -Met-tRNA^{MetM} and formyl- ^{35}S -Met-tRNA^{MetF} there was less than 15 per cent formation of acid soluble radioactivity.

Table 3. INCORPORATION OF METHIONINE FROM ACETYL- AND FORMYL METHIONYL-tRNA

tRNA	Added	c.p.m./15 μl . aliquot Incorporation at 10 min	Incorporation at 30 min
Formyl- ^{35}S -methionyl tRNA ^{MetF}	12,000	1,368	2,423
Acetyl- ^{35}S -methionyl tRNA ^{MetF}	6,600	286	566
Acetyl- ^{35}S -methionyl tRNA ^{MetM}	8,200	15	27

Reactions are described in the legend to Fig. 1; incubation was at 25° C. Acetylation of Met-tRNA^{MetM} and Met-tRNA^{MetF} followed the procedure of ref. 34.

Table 3 shows that acetyl- ^{35}S -methionyl tRNA^{MetF} is also incorporated efficiently into protein, whereas acetyl- ^{35}S -methionyl-tRNA^{MetM} is not incorporated, so that the ability of formyl or acetyl Met-tRNA^{MetF} to initiate protein synthesis is not simply to be attributed to a blocked amino group, but rather to an intrinsic property of tRNA^{MetF}.

Steps in the Initiation Process

We have used yeast Met-tRNA^{MetM}, Met-tRNA^{MetF} and fMet-tRNA^{MetF} to synthesize haemoglobin in a rabbit reticulocyte cell-free system. Because all eukaryotic cells seem to contain the same two types of methionyl-tRNAs, the use of yeast tRNAs in these experiments should not affect the results. Furthermore, *E. coli* formylmethionyl-tRNA, the initiator tRNA of bacterial protein synthesis, is also incorporated by the reticulocyte cell-free system, albeit somewhat less efficiently than the yeast tRNA (unpublished results of D. H. and H. F. L.).

Our results support the following conclusions on the mechanism of initiation of haemoglobin synthesis. (1) Both haemoglobin chains are initiated *in vitro* with a methionine residue at their amino terminus. This methionine is subsequently removed, leaving the penultimate valine as the final amino terminus. (2) Met-tRNA^{MetF} inserts methionine into the amino-terminal position of haemoglobin chains, but cannot insert methionine into internal positions. (3) Met-tRNA^{MetM} inserts methionine only into the internal positions of haemoglobin. Even when the amino group of the methionine is blocked by an acetyl group, Met-tRNA^{MetM} cannot initiate haemoglobin synthesis. (4) Rabbit reticulocyte cell extracts contain an enzyme which can remove methionine from the amino terminus of haemoglobin. Blockage of the methionine amino group by a formyl or acetyl residue inhibits the action of this enzyme. Thus when N-formyl ^{35}S -methionyl-tRNA^{MetF} is used in the cell-free system, both haemoglobin chains contain a formyl methionine residue at their amino termini.

Bacterial protein synthesis always begins with the formylated amino-acid N-formylmethionine. That yeast and liver tRNA^{MetF} can be used to initiate bacterial protein synthesis, and that yeast and *E. coli* tRNA^{MetF} can initiate haemoglobin synthesis, strongly suggests that the unique properties of the initiator methionine tRNA were conserved during evolution. But in bacteria, the initiator methionyl-tRNA must contain a formyl residue in order to initiate protein synthesis. By contrast, there

Fig. 7. Conversion of ^{35}S -Met-tRNA^{MetF} radioactivity to acid soluble form. Δ , Complete reaction; \bullet , plus chloramphenicol; \times , plus cycloheximide; \square , plus ATA. Reactions (Fig. 1) contained (where indicated) 200 $\mu\text{g}/\text{ml}$. cycloheximide, 60 $\mu\text{g}/\text{ml}$. chloramphenicol, 10^{-4} M aurintricarboxylate. A control reaction without reticulocyte extract was included. Incubation was at 37° C; 15 μl . aliquots were added to 0.5 ice-cold water, and immediately TCA to 5 per cent was added. Precipitates were collected and counted as in Fig. 1.

is no evidence for any formylated methionyl-tRNA in the cytoplasm of eukaryotic cells².

A further similarity between initiation of protein synthesis in bacteria and that of haemoglobin in rabbit reticulocytes is the fate of the N-terminal amino-acid in the final product. In *E. coli*, for instance, the N-terminal formyl methionine residue is removed in most cases through the successive use of two enzymes, a deformylase and a peptidase which removes the N-terminal methionine²⁴⁻²⁶. The observation that many bacterial proteins do contain N-terminal methionine indicates that the action of the bacterial aminopeptidase may be restricted by the nature of the amino-acid(s) adjacent to methionine. Comparison of haemoglobin sequences from several sources shows that methionine is present in the N-terminus of the β chains of beef and sheep haemoglobin²⁷. Experiments designed to show a direct incorporation of methionine from Met-tRNA^{MetF} into the β chains of sheep haemoglobin are now in progress.

Sherman *et al.* demonstrated by genetic techniques that yeast iso-1 cytochrome *c* has an AUG triplet (codon for methionine) proximal to the codon for the normal amino-terminal residue, threonine. No cytochrome *c* is produced when the AUG codon is mutated. Revertants of such mutations include second-site mutations to an AUG initiator codon at other positions in the gene; in particular they isolated several mutants which contained additional amino-acids, including an N-terminal methionine, at the beginning of the normal protein. Thus initiation of a protein produced on yeast cytoplasmic ribosomes seems also to require an AUG methionine codon^{17,18}, and it seems that initiation of protein synthesis by a special methionyl-tRNA may be a general phenomenon in the synthesis of all eukaryotic proteins.

We thank Dr Corrada Baglioni for help in techniques of haemoglobin cell-free synthesis, Drs Wilson, Sherman and Marcker for making their results known to us before publication, and Mrs Marion Jacobsen and Miss Victoria Lechner for technical assistance. This work was supported by grants from the US National Institutes of Health and from the American Cancer Society to H. F. L., from the National Institutes of Health and from the National

Science Foundation to Dr Baglioni, and by a National Institutes of Health Biomedical Sciences support grant to the Massachusetts Institute of Technology. D. H. was supported by a National Institutes of Health training grant at Brandeis University.

Factor Dependent Binding of Methionyl-tRNAs to Reticulocyte Ribosomes

by

DAVID A. SHAFRITZ
W. FRENCH ANDERSON

Section on Human Biochemistry,
National Heart and Lung Institute,
National Institutes of Health,
Bethesda, Maryland 20014

Reticulocyte initiation factors bind a formylatable methionine tRNA but not a non-formylatable tRNA. Elongation factors bind only the non-formylatable species. These findings suggest that haemoglobin chains may be initiated in a way similar to bacterial proteins.

PREVIOUS studies have indicated that three factors, M_1 , M_2 and M_3 , isolated from a 0.5 M KCl rabbit reticulocyte ribosomal wash fraction, are required in addition to the known polypeptide chain elongation factors, T_1 and T_2 , for cell-free haemoglobin synthesis at 3 mM Mg^{2+} (refs. 1-3). M_1 and M_2 can be assayed by their ability to lower the Mg^{2+} concentration optimum for poly U dependent polypeptide synthesis in the reticulocyte cell-free system, and this assay has provided a useful tool in the identification and isolation of these factors³. Because M_1 also stimulates the binding of both N-acetylphenylalanyl-tRNA and phenylalanyl-tRNA to reticulocyte ribosomes at low $[Mg^{2+}]$ ³, the role of the M factors in mammalian protein synthesis might be elucidated through the development of a triplet codon dependent binding assay based on differential responses of specific tRNAs to specific enzyme factors. Such an assay similar to the AUG and initiation factor directed binding of fMet-tRNA to washed *E. coli* ribosomes^{4,5,14} would also be useful in examining various tRNA species for special properties related to the mammalian initiation process.

Recently, Smith, Marcker and Brown^{6,7} described two species of methionine tRNAs from liver, "Met-tRNA_F" and "Met-tRNA_M", which are distinguished during cell-free ascites tumour protein synthesis in a manner similar to *Escherichia coli*: the latter inserts methionine into internal amino-acid positions of peptides and the former exclusively at the N-terminal position in response to either viral or "phased" synthetic oligonucleotide templates (oligonucleotides beginning with AUG at their 5' end). We describe here a mammalian triplet-dependent enzymatic binding assay using washed reticulocyte ribosomes, reticulocyte factors M_1 and M_2 , rabbit liver tRNA_F^{Met} and tRNA_M^{Met}, and the trinucleotide codon

AUG. In this system, Met-tRNA_F binds to ribosomes enzymatically at low $[Mg^{2+}]$ in response to M_1 plus M_2 , but poorly in response to T_1 . By contrast, Met-tRNA_M binds to washed reticulocyte ribosomes in response to T_1 , but not to M_1 plus M_2 . These data indicate that the factors M_1 plus M_2 can specify binding of the mammalian counterpart to a known bacterial initiator tRNA to the ribosome and can distinguish this tRNA from a non-initiator tRNA, which is acylated with the same amino-acid and responds to the same trinucleotide codon signal.

Triplet-Dependent Enzymatic Binding Assay

When we studied standard ribosomes washed with 0.5 M KCl for their ability non-enzymatically to bind

Table 1. REQUIREMENTS FOR BINDING OF Met-tRNA TO RETICULOCYTE RIBOSOMES AT 5 mM Mg^{2+}

Deletions or substitutions to reaction mixture	A pmoles ³ H-Met-tRNA bound	B pmoles ³ H-fMet-tRNA bound
Complete system	1.07	1.10
Minus M_1	0.30	0.16
Minus M_2	0.54	1.23
Minus M_1 and M_2	0.24	0.13
Plus ribosomal wash fraction	0.81	—
Plus 105,000g supernatant	0.37	—
Minus ribosomes	0.08	0.07
Minus AUG	0.40	0.25
Minus GTP	0.43	0.65
Minus M_2 , minus GTP	—	0.93

Experimental conditions are described in the legend to Fig. 1. Where indicated 78 μ g ribosomal wash protein or 0.5 mg 105,000g supernatant protein was added to the reaction mixture. In the complete system less than 0.08 pmoles of hot trichloroacetic acid precipitable material was retained on the nitrocellulose filter. (A) 10 pmoles of unfractionated rabbit reticulocyte ³H-Met-tRNA were used in each incubation. (B) 10 pmoles of unfractionated rabbit reticulocyte ³H-fMet-tRNA (60 per cent formylated) were used in each incubation.

Fig. 1. Kinetic parameters for the triplet dependent enzymatic binding of ^3H -Met-tRNA to rabbit reticulocyte ribosomes at 5 mM Mg^{2+} . Reticulocyte ribosomes and the ribosomal wash factors M_1 and M_2 were prepared as previously described³ with the additional steps: ribosomes were washed a second time in standard sucrose (0.25 M sucrose, 1 mM dithiothreitol, 0.1 mM EDTA, potassium salt, pH 7.0) made 0.5 M in KCl; M_1 and M_2 were separately chromatographed on 'Sephadex G-150' after their original isolation by DEAE-cellulose chromatography (procedures as described in ref. 3). The sequenced trinucleotide ApUpG was purchased from Miles Laboratories; high voltage electrophoresis revealed one major and four minor bands. The major band represented authentic AUG and contained approximately 50 per cent of the total A_{260} units in the preparation. Enzymatic binding of ^3H -Met-tRNA to washed reticulocyte ribosomes was performed by a modification of the nitrocellulose filter assay originally reported by Nirenberg and Leder¹⁴. Incubations, in a total volume of 50 μl ., were performed at 23°C and contained 20 mM Tris-HCl (pH 7.5), 100 mM KCl, 5 mM MgCl_2 , 0.2 mM GTP (neutralized to pH 7.0 with KOH), 1 mM dithiothreitol, 10 pmoles ^3H -Met-tRNA (unfractionated rabbit reticulocyte tRNA¹³ acylated 3.4 per cent with L- ^3H -methionine, specific activity 2,500 mCi/mole), 15 μg M_1 protein, 6.3 μg M_2 protein, and ribosomes and AUG concentration as indicated. The reactions were stopped by addition of 3 ml. of wash buffer (20 mM Tris-HCl (pH 7.5)—100 mM KCl—5 mM MgCl_2 , 4°C). The reaction mixture was then immediately filtered on a nitrocellulose filter, washed three times with 3 ml. wash buffer at 4°C, and counted in a liquid scintillation spectrometer as previously reported³. A blank of 0.03 pmoles, representing the activity observed in the absence of both ribosomes and factors, was subtracted from each point. A, Ribosome concentration curve determined at a 2 min time point with 0.15 A_{260} units of AUG. B, Time course of reaction determined with 1.1 A_{260} units of ribosomes and 0.15 A_{260} units of AUG. C, AUG concentration curve determined at a 2 min time point with 1.1 A_{260} units of ribosomes.

unfractionated reticulocyte ^3H -Met-tRNA at high $[\text{Mg}^{2+}]$, little activity was obtained with the triplet AUG. When twice washed reticulocyte ribosomes were used, however—see legend to Fig. 1 for experimental procedures—activity was markedly increased. We then found that similar triplet dependent binding could be obtained enzymatically at low $[\text{Mg}^{2+}]$ by introducing the crude ribosomal wash fraction (Table 1A). Crude supernatant or partially purified reticulocyte T_1 worked poorly. M factors, which had been completely separated from T_1 and T_2 by a combination of DEAE-cellulose and 'Sephadex G-150' chromatography, were then tested for their ability to replace crude ribosomal wash in AUG dependent enzymatic binding of unfractionated ^3H -Met-tRNA. M_1 could partially replace the crude wash fraction, but activity was markedly enhanced by the further addition of M_2 . This AUG mediated binding of Met-tRNA to reticulocyte ribosomes at 5 mM Mg^{2+} was almost completely dependent on GTP (Table 1A).

Table 1B shows the influence of an N-formyl group on the binding reaction. When formylated, unfractionated methionine tRNA (fMet-tRNA, approximately 60 per cent formylated) was used as substrate, there was a minimal increase in binding in the presence of M_1 plus M_2 , and AUG dependence remained unchanged. But, with this substrate (fMet-tRNA), there was a complete loss of the M_2 requirement, a partial loss of GTP dependence, and a rise in the $[\text{Mg}^{2+}]$ optimum for enzymatic binding (data not shown).

The kinetic curves for the ribosome concentration, time, and AUG concentration which characterize the triplet dependent enzymatic binding assay, are given in Fig. 1A, B and C. In subsequent studies, 1.1 A_{260} units of ribosomes, a 2 min reaction time, and 0.15 A_{260} units

of AUG were used. Using unfractionated rabbit liver ^3H -Met-tRNA as substrate, we performed enzyme concentration studies at 5 mM Mg^{2+} for both M_1 and M_2 (Fig. 2A, B). Significant triplet mediated activity was obtained with M_1 alone, but not with M_2 alone. Maximum activity required both M_1 and M_2 . Saturating enzyme levels, 15 μg M_1 protein and 6.3 μg M_2 protein per 50 μl . reaction mixture, were used in all subsequent studies.

Factor Dependent Binding of Met-tRNA^f and Met-tRNA^{Met}

To examine factor specificity in the binding of the two types of methionyl-tRNA, that is, formylatable (tRNA^{fMet}) and non-formylatable (tRNA^{Met}), the tRNA^{Met} species from rabbit liver tRNA were separated by 'Freon' reversed phase (RPC-2) chromatography^{8,9}. Fractions containing tRNA^{Met} were identified by acylation with crude reticulocyte synthetase, and three principal peaks were obtained (Fig. 3). The Met-tRNA from fractions 15 (peak I), 17 (peak II) and 21 (peak III) were then tested for their ability to be formylated with crude *E. coli* transformylase¹⁰. After a 30 min incubation period, 100 per cent of the Met-tRNA in peak I and 88 per

Fig. 2. M_1 and M_2 enzyme saturation curves for AUG dependent binding of ^3H -Met-tRNA to reticulocyte ribosomes at 5 mM Mg^{2+} . Experimental details are described in the legend to Fig. 1 and in the text. A blank of approximately 0.29 pmoles, representing the sum of the activities obtained with ribosomes alone and with M_1 and/or M_2 as a function, was subtracted from each value. A, ^3H -Met-tRNA binding as a function of M_1 concentration (μg protein per 50 μl . reaction mixture). Upper curve: in the presence of 6.3 μg M_2 protein; lower curve: in the absence of M_2 . Fig. 3. Fractionation of rabbit liver tRNA by 'Freon' reversed phase chromatography (RPC-2). Details of this preparative column have been published⁹. Column fractions, which had been stored lyophilized at -20°C, were tested for methionine acceptance as described in the text. The arrows indicate the three fractions tested for their ability to be formylated (see text). The material from fractions 17 and 21 was used for the studies shown in Figs. 4 and 5, respectively.

cent in peak II were formylated, whereas only 7.9 per cent of the Met-tRNA in peak III was formylated. The ability of each Met-tRNA species to bind enzymatically to reticulocyte ribosomes in response to AUG was then tested. Both peaks I and II (Met-tRNA_I) were enzymatically bound to ribosomes with M₁ plus M₂, whereas peak III was inactive. By contrast, when T₁ was used as the binding enzyme, only peak III (Met-tRNA^{Met}) was actively bound to ribosomes. Figs. 4 and 5 show curves for the dependence on [Mg²⁺] of the binding with Met-tRNA_I (peak II) and Met-tRNA^{Met} (peak III), respectively. With Met-tRNA_I as substrate (Fig. 4A), M₁ plus M₂ are most active at low [Mg²⁺]; T₁ is poorly active at low [Mg²⁺], but becomes progressively more active as [Mg²⁺] is raised toward 10 mM. These observations become more apparent when the contribution by non-enzymatic binding (that obtained in the absence of added enzyme factors not distinguishing between possible ribosomal binding sites) is subtracted from total bound radioactivity (Fig. 4B). With this substrate (Met-tRNA_I), the binding reaction with T₁, as well as that with M₁ plus M₂, is dependent on both AUG and GTP. When Met-tRNA^{Met} is used (Fig. 5A, B), T₁ is highly active, M₁ poorly active (data not shown) and M₁ plus M₂ totally inactive. In the conditions used, the enzymatic binding of Met-tRNA^{Met} to ribosomes with T₁ is GTP dependent, but not AUG dependent.

Specificities

The studies by Smith, Mareker and Brown^{6,7} indicated that Met-tRNA_I may be a specific initiator tRNA in the ascites tumour cell-free system in response to both artificial and viral messages. But this does not mean that Met-tRNA_I is the only mammalian initiator. In other reports, several N-blocked aminoacyl-tRNAs have been suggested as possible initiators in various mammalian systems: N-blocked valine-tRNA for haemoglobin¹¹, PCA-tRNA for immunoglobulins¹², and N-acetylserine-tRNA for histones¹³. In this investigation, using our mammalian triplet dependent enzymatic tRNA binding assay, we have found that Met-tRNA_I specifically responds to M₁ plus M₂ at low [Mg²⁺] and the reaction is both AUG and GTP dependent. There is no apparent requirement for a blocking group, although this does not mean that a blocking group is not formed transiently during the incubation period. With Met-tRNA^{Met} as

Fig. 4. Mg²⁺ dependence for AUG-dependent binding of ³H-Met-tRNA_I to reticulocyte ribosomes. The source of the tRNA^{Met} was fraction 17 from Fig. 3. Each 50 μ l reaction mixture contained 8 pmoles ³H-Met-tRNA_I (L-³H-methionine, specific activity 2,500 mCi/nmole), 24 μ g T₁ protein where indicated, and other components as listed in the legend to Fig. 1. For each point, the wash buffer contained the same [Mg²⁺] as the reaction mixture. A blank of 0.03 pmoles, representing the activity observed in the absence of both ribosomes and factors, was subtracted from each point. A, ³H-Met-tRNA_I binding to reticulocyte ribosomes in the presence of M₁ plus M₂, T₁, or in the absence of added factors (non-enzymatic binding). B, Same data as in A but with the contribution by non-enzymatic binding subtracted from each point.

Fig. 5. Mg²⁺ dependence for the binding of ³H-Met-tRNA^{Met} to reticulocyte ribosomes. The source of the Met-tRNA^{Met} was fraction 21 in Fig. 3. Experimental conditions were the same as for Fig. 4. A, ³H-Met-tRNA^{Met} binding to reticulocyte ribosomes in the presence of T₁, M₁ plus M₂, or in the absence of added factors (non-enzymatic binding). B, Same data as in A but with the contribution by non-enzymatic binding subtracted from each point.

substrate, there is a reversal of enzyme specificity, so that activity is obtained with T₁ rather than M₁ plus M₂. This reaction is dependent on GTP but not, apparently, on AUG.

The exact relationship of this binding assay to the role of M₁ and M₂ in reticulocyte protein synthesis is still not clear. In appropriate conditions, M₁ alone seems to recognize various blocked as well as unblocked aminoacyl-tRNAs (ref. 3 and unpublished observations). M₂ alone, on the other hand, is inactive with all tRNAs tested. The loss of M₂ as well as GTP dependence for the binding of fMet-tRNA by contrast with that of Met-tRNA (as shown in Table I) is also not clear.

Our findings indicate that in appropriate experimental conditions, reticulocyte ribosomes can be utilized in a triplet dependent, enzymatic tRNA binding assay and that the tRNA species, Met-tRNA_I, and the enzyme factors, M₁ and M₂, have roles in the reticulocyte system compatible with the known mechanism for the initiation of protein synthesis in bacterial cells. These results cannot, however, be taken as proof that Met-tRNA_I is a natural initiator in the reticulocyte cell-free system, because the tRNA species and/or the enzyme factors could conceivably represent only vestigial activities in the mammalian system. We hope to determine whether the initiation of haemoglobin synthesis in a tRNA-dependent cell-free haemoglobin synthesizing system depends on the addition of tRNA^{Met}, to examine other tRNAs for initiator properties, to look for initiation specific peptide bond formation, and to use natural haemoglobin messenger as the initiator signal in the binding assay.

We thank Miss Patricia J. Hogan and Mr Dante Picciano for assistance.

Reactions of Haemoglobin Dimers after Ligand Dissociation

by

G. L. KELLETT

H. GUTFREUND

Molecular Enzymology Laboratory,
Department of Biochemistry,
University of Bristol,
University Walk, Bristol BS8 1TD

The absorption spectra of haemoglobin solutions containing varying proportions of tetramer and dimer were followed immediately after the removal of oxygen. Two parallel reactions involving conformational transitions contribute to the observed spectral change: a first order reaction of the dimer which need not be cooperative and a very much faster reaction of tetramer which can be controlled by the second order association of dimer to tetramer.

For more than sixty years, theoretical and experimental investigations of haemoglobin have been concerned with the study of the nature of the molecular interactions which result in the cooperative binding of oxygen¹. It is this property of haemoglobin which, by narrowing the range of the oxygen pressure controlling uptake and release, is responsible for its efficiency in oxygen transport.

In the erythrocyte, haemoglobin occurs as a tetramer, consisting of two α and two β chains, and may exist as either a constrained or an unconstrained form in the absence or presence of ligand respectively. The constrained tetramer is characterized by a lower affinity for and a slower rate of combination with ligand than the unconstrained tetramer². Further, the X-ray studies of Perutz and his collaborators have shown in remarkable detail how the quaternary structures of the two forms differ^{3,4}. It is the change in conformation from one structure to the other on ligand binding which forms the basis of the cooperative phenomena. In solution studies, therefore, our principal interest must be the elucidation of the sequence of events within the tetramer which bring about the conformational change.

While this problem remains, another important question has been debated in the past twenty years⁵. In the concentration range (10^{-2} – 10^{-4} M haem) normally used to study haemoglobin reactions, dissociation of the tetramer to dimer occurs. At present no agreement has been reached concerning whether or not there are distinct properties of the dimer and tetramer in their reactions with ligand^{2,6–14}. Here this question is approached by correlating kinetic features with the fraction of dimer determined from measurements of the tetramer–dimer dissociation equilibrium. Although there is general agreement on the value of equilibrium constants for the liganded molecule^{10,15–20}, there are conflicting data concerning the non-liganded molecule^{2,10,17,19}. For the necessary correlation it was decided therefore to investigate the slow spectral change^{21,22} occurring immediately after removal of ligand in two sets of conditions, one in which tetramers and dimers coexist and one in which there is essentially all dimer.

To describe these reactions of haemoglobin in dilute solution we propose a simple kinetic model in which two reactions contribute to the slow spectral changes observed in dilute salt and neutral pH. The first reaction is a slow first order process ($t_1 \approx 3.5$ s) representing a conformational change within the dimer. The second reaction is the extremely fast ($t_2 < 100$ μ s) conformational change of the tetramer. In the experimental conditions, however, this reaction is kinetically controlled by the slow second order association of dimer to tetramer. The reason that the slow first order process has not been previously identified in haemoglobin reactions, even though the consequences of conformational transition are well known, is that it is masked by the second order dimer–dimer association reaction which occurs in parallel. It is shown that the

proposed model is consistent with a wide range of experimental haemoglobin data presented in the literature.

"Base-line Drift"

In all experiments reported here, the removal of the ligand oxygen has been effected by mixing oxyhaemoglobin in the stopped-flow apparatus with a solution of sodium dithionite. This solution, in which sodium dithionite was at a concentration of 2 mg/ml. before mixing, was prepared by dissolving the solid in deoxygenated buffer. The pH of the buffer was adjusted with NaOH before the addition of dithionite to compensate for the increase in acidity caused by solution of the dithionite.

Fig. 1 shows a stopped-flow trace recorded at 429 nm on the removal of oxygen from oxyhaemoglobin in 1 M NaI (pH 7.0) buffer at a concentration of 6.2μ M haem before mixing. The removal of oxygen, represented by the curve AB, is complete after about 100 ms. But the base-line recorded after about 60 s, represented by CD, is not coincident with that observed immediately after the initial removal of oxygen. Fig. 2a shows the recording of this difference observed in 1 M NaI at high sensitivity. Such base-line drifts have been noted previously (Gibson and Roughton, unpublished data quoted by Gibson²¹), and drifts of a similar nature, though over a longer time scale, have been attributed to side effects caused by the use of dithionite.

Antonini *et al.*, however, in their key paper²² on the kinetics of haemoglobin reactions, have concluded that such drifts occurring within seconds of the removal of oxygen by dithionite, are in fact real kinetic features of the haemoglobin system. Evidence for this conclusion is afforded in a general sense by the reproducibility of

Fig. 1. Stopped-flow record of the rapid deoxygenation of oxyhaemoglobin in 1 M NaI (pH 7.0). Concentrations before mixing, 6.2μ M haem and 2 mg/ml. dithionite; 1 cm grid, scan time 50 ms/cm; 429 nm.

Fig. 2. *a*, Amplification of the "drift" phase BD (Fig. 1) in 1 M NaI (pH 7.0). Scan time 2 s/cm; other conditions as for Fig. 1. *b*, "Drift" phase observed at the same concentration as for *a* in 0.09 M NaCl (pH 7.0). Concentrations before mixing, 6.2 μ M haem and 2 mg/ml dithionite; scan time 0.5 s/cm; 429 nm.

both the amplitude and the velocity of the drift. More specifically, it is shown in control experiments repeated here with single chains, α^{SH} , that no such drifts occur at neutral pH either in 0.09 M NaCl or in 1 M NaI. Thus they cannot be caused by side effects of dithionite. Further, there is a characteristic difference spectrum in the Soret region between unliganded haemoglobin before and after the drift (Fig. 3). The maximum observed at 429 nm was used to follow the reactions here. The drift cannot be caused by slow oxygen dissociation from sites of abnormally high affinity since the difference spectrum is distinct in form from that between oxy and unliganded haemoglobins. The conclusion reached by Antonini *et al.*²² that this base-line drift is in fact a real kinetic feature of the haemoglobin system is amply confirmed by the experiments discussed here.

A Dimer Reaction expressed by the "Drift"

To identify the "drift" reaction with a particular species, it is necessary to have a detailed knowledge of the tetramer-dimer dissociation equilibrium of oxyhaemoglobin in the two sets of experimental conditions used in this investigation, namely 1 M NaI and 0.09 M NaCl at pH 7.0 (0.01 M Tris, 10^{-3} M EDTA). In similar conditions, the formation of monomer²⁴ in dilute solutions (10^{-6} to 10^{-7} M haem) has been shown to be irreversible and to be inhibited by 10^{-3} M EDTA (unpublished results of G. L. K.). In the presence of EDTA, the tetramer-dimer dissociation equilibrium constant, $K_{4,2}$, was then determined by sedimentation equilibrium to be 2.9 μ M haem in 0.09 M NaCl (pH 7.0) in good agreement with the value of 2.5 μ M haem from gel-filtration studies²⁰. In 1 M NaI, $K_{4,2}$ was tentatively estimated to be about 6.2 mM haem.

Thus within the present range of kinetic observation from 2.1 to 16 μ M haem, oxyhaemoglobin is completely in the form of dimer in 1 M NaI, whereas in 0.09 M NaCl the fraction of dimer varies between about 0.65 and 0.35.

Fig. 4 shows that the amplitude of the "drift" phase is directly proportional to oxyhaemoglobin concentration in 1 M NaI. To determine whether or not the "drift" phase may be correlated with either the dimer or the tetramer, the concentration dependence of its amplitude was then studied in 0.09 M NaCl (pH 7.0). In these conditions at a concentration of 6.2 μ M haem, the amplitude of the "drift" phase was found within experimental error to be half (Fig. 2*b*) of that found in 1 M NaI (Fig. 2*a*). At this concentration oxyhaemoglobin is 50 per cent dissociated into dimer in 0.09 M NaCl and completely dissociated in 1 M NaI, so that the "drift" phase must be correlated with the dimer.

The fraction of dimer was therefore calculated at each concentration examined by comparing the amplitude in 0.09 M NaCl with that in 1 M NaI at the same total concentration. The fraction of dimer versus the total concentration before mixing is shown in Fig. 5. The concentration before mixing was used in this correlation for the dissociation rate of oxyhaemoglobin from tetramer to dimer in dilute salt is relatively slow ($t_{1/2}$ of the order of 1 s) compared with the rate of oxygen dissociation. Thus the removal of oxygen was effected here before any detectable increase could be observed in the fraction of dimer over that present before mixing due to dissociation upon dilution in the stopped-flow apparatus. The solid curve in Fig. 4 is drawn for a tetramer to dimer dissociation constant of 3.1 μ M haem. This compares well with the values of 2.5 and 2.9 μ M haem determined by gel-filtration and sedimentation equilibrium, respectively, in the same conditions. The correlation of the slow phase with the dimer clearly implies that the equivalent spectral change due to the tetramer occurs relatively quickly, and indeed in the conditions expressed in Fig. 5 must be complete with the completion of oxygen removal.

At low oxyhaemoglobin concentrations, plots of $\ln \Delta A$ versus t are close to linearity. In the initial stages of the "drift" phase, there is present in the plot some slight curvature, which becomes pronounced only at higher concentrations. In the latter instance, plots of $1/\Delta A$ versus t are close to linearity in the initial stages and deviate only in the later stages. The combination of these features is evident in the biphasic nature of the "drift" phase seen at 6.2 μ M haem in 0.09 M NaCl (Fig. 2*b*). These observations suggest strongly that the principal reactions of the slow phase may well be first and second order reactions of the dimer and its products producing similar spectral changes.

Fig. 3. Spectrum of the change in extinction, ΔE_{mM} (haem), represented by the "drift" phase in 1 M NaI (pH 7.0). Observations were made at a concentration of 6.2 μ M haem after mixing.

Kinetic Model for the "Drift" Phase

The dimer produced by the dissociation of oxyhaemoglobin tetramer in dilute salt at neutral pH is the $\alpha_1\beta_1$ dimer^{3,25-27}. The principal feature of the following reaction sequence is that it assumes that the $\alpha_1\beta_1$ dimer may undergo a conformational change. In this scheme, species having the characteristic conformation of the final constrained, unliganded form at equilibrium are denoted by an asterisk, whereas the species in the initial unconstrained, liganded form have no asterisk.

Immediately on removal of ligand, the unliganded dimer so produced has the unconstrained, liganded conformation, D. This may then undergo a conformational transition represented by reaction 1 to the constrained conformation, D*. The constrained dimer may subsequently associate with another one to form the constrained tetramer, T*, by reaction 5. The reverse reaction 6 must also exist, however slow this may be compared with reaction 5. Alternatively, rather than undergo the conformational transition 1, the unconstrained, unliganded dimer, D, may associate with a like dimer to produce an unconstrained tetramer, T, expressed in reaction 2. This tetramer may then either dissociate according to reaction 3, so defining the dissociation-association equilibrium characteristic of the fully liganded molecule, or it may change by reaction 4 to the constrained tetrameric conformation, T*.

We assume that reactions 5 and 6 involve no spectral changes and are consequently not seen in the "drift" phase. This assumption means that no knowledge of the dissociation-association equilibrium between the constrained tetramer and dimer is required for this analysis. In these circumstances, the problem is primarily resolved by a comparison of the rate of dissociation of the unconstrained tetramer, reaction 3, with the rate at which the tetramer changes conformation, reaction 4. At neutral pH in dilute salt, the rate of dissociation of liganded, unconstrained tetramer is relatively slow. The value of t_4 is approximately 1.4 s in 0.1 M phosphate (pH 7.0)^{22,28}. By comparison, the rate of the tetramer conformational change is a fast process: $t_4 < 1$ ms. Thus the "drift" phase correlates simply with the fraction of dimer, implying that the equivalent tetrameric change is completed with the fast removal of ligand. Alternatively, the fraction of "rapidly reacting haemoglobin" correlates directly with dimer in dilute salt at neutral pH¹³, showing that the tetramer changes conformation more quickly than ligand

Fig. 4. The amplitude (ΔA) of the "drift" phase as a function of total haemoglobin concentration (haem) before mixing in 1 M NaI (pH 7.0).

Fig. 5. The fraction of dimer as a function of total concentration before mixing in 0.09 M NaCl (pH 7.0). The fraction of dimer (\circ) was determined by comparing the amplitude of the "drift" phase in 0.09 M NaCl with that in 1 M NaI at the same total concentration. The solid curve is calculated for a dissociation constant of $3.1 \mu\text{M}$ haem.

can combine with the tetramer even in its rapidly reacting form. Further, it has been shown by Antonini and Brunori²⁹, using the change in reactivity of the β -93 sulphhydryl group as an index of conformation change, that the transition from constrained to unconstrained conformation must occur within a time rather less than the dead-time of a stopped-flow apparatus, that is, less than 1 ms.

In dilute salt at neutral pH therefore, if reaction 2 occurs, reaction 4 will always occur in preference to reaction 3 and reaction 2 will be the rate-limiting step. The reaction scheme then reduces simply to equations 1 and 2

For this simple case of parallel first and second order reactions producing the same spectral change, it is readily shown that

$$t_4 = \frac{1}{k_1} \ln \left[\frac{k_2 + 0.5 k_2 D_0}{k_1 + k_2 D_0} \right] + \frac{\ln 2}{k_1} \quad (7)$$

where D_0 is the concentration of the unconstrained dimer at time $t=0$. Fig. 6 shows the concentration dependence of t_4 observed in 0.09 M NaCl (pH 7.0) analysed in terms of equation 7. The concentration of dimer (expressed in μM haem) was calculated from the fraction of dimer at the haemoglobin concentration before mixing. The concentration so calculated was then halved before the application of equation 7 to correct for dilution in the cell. The solid curve was computed with the values of k_1 and k_2 of 0.20 s^{-1} and $4.3_5 \times 10^5 \text{ M}^{-1} \text{ s}^{-1}$ respectively. Because k_2 is the association rate constant of unconstrained dimers, it is now possible to calculate k_3 , the dissociation rate constant, from a knowledge of the dissociation equilibrium constant, $3.1 \mu\text{M}$ haem, in 0.09 M NaCl (pH 7.0). The value of k_3 is found to be 1.3_6 s^{-1} corresponding to t_3 for the dissociation reaction of approximately 0.5₁ s.

The Fast Dimer is Slow

We have presented kinetic observations of spectral changes in haemoglobin solutions immediately after the removal of ligand. They provide evidence for a first order reaction characterizing a slow conformational change of the dimer which reacts rapidly with ligand in flash photolysis experiments, and for a very much faster

Fig. 6. The dependence of t_d for the "drift" phase in 0.09 M NaCl (pH 7.0) on the concentration of dimer (see text). The solid curve is calculated by the application of equation 7 using values of k_1 and k_2 of 0.20 s^{-1} and $4.3 \times 10^5 \text{ M (haem)}^{-1} \text{ s}^{-1}$.

change within the tetramer. We now wish to show how the present results can be used to interpret some of the interesting experiments reported in the literature on the behaviour of solutions containing varying proportions of tetramer and dimer.

After the flash photolysis of carboxyhaemoglobin the recombination curve of haemoglobin with CO is biphasic³⁰, the fast phase representing a reaction some forty times faster than that of the slow phase. The first observation is that in dilute salt at neutral pH the percentage of "rapidly reacting haemoglobin" correlates directly with the percentage of dimer¹³ (see Fig. 5). This rapid rate, however, is very similar to that of the isolated α and β chains. These are well known not to undergo a conformational transition on ligand binding and they thus exhibit hyperbolic saturation curves characteristic of a non-cooperative binding process. Using this criterion as an index of the absence of cooperativity, it has been concluded that the dimer is devoid of cooperativity¹³. But clearly such a correlation is also to be expected on the basis of the present finding that the conformational change within the dimer and the conversion of dimer to slowly reacting tetramer are relatively slow processes. The correlation follows directly from the fact that the rate of the tetramer conformation change, $t_4 < 100 \mu\text{s}$, is much faster than the rate at which ligand binds with "rapidly reacting haemoglobin"— t_2 generally of the order of 2 to 10 ms—which in turn is much faster than the rate at which the dimer either changes conformation or associates to tetramer: t_1 of the order of seconds. Thus the initial tetramer changes to its slowly reacting form almost instantaneously on flash photolysis before it can recombine with ligand; the ligand combines preferentially with the dimer in the unconstrained, rapidly reacting conformation, and then subsequently with slowly reacting tetramer.

This sequence of events also explains why the percentage of "rapidly reacting haemoglobin" decreases²² with increasing time of illumination causing dissociation of CO from carboxyhaemoglobin. The increased time over a period of seconds simply allows more time for the dimer to change to a constrained form which associates strongly to the slowly reacting, constrained tetramer or for the dimers to associate before the fast tetramer conformation change from the unconstrained form. A plot of the percentage of "rapidly reacting haemoglobin" against length of illumination is thus equivalent to observing the "drift" phase directly. This situation is represented in Figs. 3 and 6 of the article by Antonini *et al.*²².

The second observation is that the percentage of "rapidly reacting haemoglobin" in high salt solutions at neutral pH or in acetate solutions is always less (as much as 20 per cent less) than the percentage of dimer by contrast with the situation in dilute salt at neutral pH. This observation stems at least in part from the fact that the second order association step of unliganded, unconstrained dimers, reaction 2, becomes competitive with rate at which ligand binds to "rapidly reacting haemoglobin". Experiments designed to correlate a reaction property with the dimer species are necessarily performed at concentrations around the equilibrium dissociation constant of tetramer to dimer. In 0.09 M NaCl (pH 7.0); 2 M NaCl (pH 7.0); and 0.25 M acetate (pH 5.4), the half-dissociation points are 6.2 μM , 82.3 μM and 0.56 mM in haem, respectively. Simple steric considerations^{3,31} suggest that the association rate constant of unconstrained dimers ($4.3 \times 10^5 \text{ M}^{-1} \text{ s}^{-1}$ in 0.09 M NaCl, pH 7.0) is similar for each condition, so that if the fast reacting dimer disappears entirely through the self-association step, the t_1 values for each half-dissociation point are 0.74 s, 56 ms and 8.2 ms, respectively. Within the concentration range investigated here, the value of t_1 observed in conventional flash photolysis experiments for the combination of CO with "rapidly reacting haemoglobin" varies from approximately 10 ms in dilute salt to about 2 ms in concentrated salt solutions.

Thus within the concentration range of each experiment, the t_1 in dilute salt for the second order self-association step is very much slower than that for the rapid combination of ligand whilst the rates of the two processes in high salt and acetate become comparable. Thus in these cases, particularly so for acetate, the second order process actually converts some rapidly reacting dimer to slowly reacting tetramer, by way of reactions 2 and 4, before the ligand can react with dimer to result in the observation that the percentage of "rapidly reacting haemoglobin" is always less than that of the dimer.

Two Kinds of Dimer ?

The long held persuasion that the dimer possesses the full cooperative characteristics of haemoglobin has rested primarily on the observation that the ligand binding characteristics of haemoglobin are not significantly affected by changes in conditions known to alter the tetramer-dimer equilibrium of oxyhaemoglobin^{2,5-12,14}. In particular, the value of n in the Hill plot remains close to 2.7 even in conditions where the tetramer is believed to be substantially dissociated to dimer in both the unconstrained and constrained forms^{10,17,18}.

The postulated "cooperative dimer" has been reconciled¹² with evidence from flash photolysis of a "non-cooperative" dimer¹³ by the suggestion that the unconstrained and constrained tetramers dissociate across different planes to form alternatively $\alpha_1\beta_1$ and $\alpha_1\beta_2$ dimers (Perutz notation), characterized by fast and slow reaction with ligand respectively. This is consistent with the fact that constrained haemoglobin is always all slowly reacting in stopped-flow experiments²¹. The flash data are explained by assuming that the equilibrium between the dimers is completely in favour of $\alpha_1\beta_1$ in dilute salt at neutral pH, but is towards $\alpha_1\beta_2$ in high salt and acetate.

We now have to examine whether the first order step arises from a rate limiting dissociation reaction 8 of $\alpha_1\beta_1$ to single chains prior to reassociation to $\alpha_1\beta_2$:

Because the dimer-monomer equilibrium constant, $K_{2,1}$, in 0.09 M NaCl (pH 7.0) is not greater than $6.2 \times 10^{-9} \text{ M haem}$ (unpublished results of G. L. K.), and because the association rate constant of single chains in comparable conditions³² is approximately $8 \times 10^5 \text{ M}^{-1} \text{ s}^{-1}$, the minimum t_1 for reaction 8 is approximately 140 s. This value may

well be several orders of magnitude less than the real one, for hybridization data³³ suggest that $K_{2,1}$ is probably substantially less than 6.2×10^{-9} M haem. An $\alpha_1\beta_2$ model cannot therefore account for the observed t_1 of 3.5 s.

Consequences of the postulate that $\alpha_1\beta_1$ and $\alpha_1\beta_2$ dimers may coexist in certain conditions in appreciable fractions are that the interactions across the $\alpha_1\beta_1$ and the $\alpha_1\beta_2$ contact surfaces respectively must be comparable in strength and appreciable amounts of monomer must be formed. The monomer is a fast reacting species so that the percentage of "rapidly reacting haemoglobin" should be greater than the percentage of dimer. This is not observed. Furthermore, molecular weight studies in acetate^{18,19} reveal no molecular weights below the dimer value.

We conclude therefore that the data are better explained in terms of one kind of dimer, $\alpha_1\beta_1$, which may undergo a slow conformational change and conversion to constrained tetramer on ligand removal.

No Unliganded Dimer

The observed conformation change of the dimer was induced by ligand removal from both sites and does not provide any evidence about its cooperativity. It is, however, possible to predict the percentage of dimer in 0.09 M NaCl by comparison of the "drift" phase amplitudes in 0.09 M NaCl and 1 M NaI. Because both sets of conditions start from unconstrained $\alpha_1\beta_1$ dimers, such a prediction implies that the final unliganded, constrained equilibrium states must be spectrally equivalent. This situation requires either that the constrained dimer and tetramer have equivalent conformations, and are therefore presumably similar in cooperative binding properties, or that the constrained tetramer is not dissociated appreciably in either salt condition. This interpretation is also required by the stoichiometric titration of unliganded haemoglobin showing linear uptake of carbon monoxide³⁴.

It seems that the decision between the two alternatives must rest on molecular weight studies on unliganded haemoglobin which are fraught with technical difficulties. The present kinetic analysis, however, does not assume nor require any knowledge of the tetramer-dimer dissociation-association properties of constrained, unliganded haemoglobin. Recently, an extensive investigation of these properties (unpublished results of G. L. K.), in which a number of technical problems have been identified, has led to the finding that at concentrations as low as 6.2×10^{-7} M haem, the molecular weights at neutral pH in 0.09 M NaCl, 2 M NaCl and 1 M NaI are all greater than 60,000 daltons. Because these conditions vary greatly in their ability to dissociate oxyhaemoglobin, it has been concluded that there is no appreciable dissociation of constrained, unliganded tetramer within this concentration range. These results afford an explanation of why the value of n should be apparently independent of the state of aggregation of oxyhaemoglobin. In a wide range of conditions used to determine oxygen equilibrium curves, even in high salt concentrations, the unliganded, constrained tetramer would be undissociated. All cooperative effects could then take place in the tetramer which would dissociate to dimers only after the reaction with ligand had occurred and the structure of the tetramer changed to that of the liganded form. X-ray analysis⁴ shows that the subunits in the unliganded, constrained haemoglobin tetramer are strongly cross-linked by the C-terminal residues; these make the tetramer very stable. In this case, even if the dimer is completely non-cooperative (and the conformational change observed is associated with the Bohr effect^{35,36}) no rapidly reacting component of unliganded haemoglobin will be seen in stopped-flow experiments since it is effectively all tetrameric.

The present data clearly show that in 0.09 M NaCl (pH 7.0), the t_1 for the conformational change of the tetramer (probably not greater than 100 μ s) is a factor

at least 3.5×10^4 faster than that for the dimer (3.5 s). This information is of particular importance in assessing the relative efficiencies of the two major subunit contacts within the tetramer, $\alpha_1\beta_1$ and $\alpha_1\beta_2$, in transmitting the interactions which are the basis of cooperativity. Because the type of dimer which would exist in 0.09 M NaCl (pH 7.0) is believed to be $\alpha_1\beta_1$, our findings suggest that the $\alpha_1\beta_1$ contact region by itself is kinetically incompetent in transmitting interaction changes induced as a result of ligand removal (or probably binding). Although it is not possible to deny that a combination of both $\alpha_1\beta_1$ and $\alpha_1\beta_2$ contacts might be responsible for the very fast tetramer conformational change, it seems probable that the major contributory factor is due to a particularly efficient transmission of interactions (including terminal residues) across the $\alpha_1\beta_2$ contact surfaces. This interpretation is consistent with the structural findings of the X-ray investigations which show that the $\alpha_1\beta_1$ contact surfaces are intertwined and hardly show any movement during ligand binding and release; by contrast the $\alpha_1\beta_2$ contacts show extensive movement and display side chain amino-acid distortion (unpublished observations of H. Muirhead and J. Greer).

Some caution must be expressed concerning the simple analysis presented here, for the formation of tetramer hybrids of the type DD* has not been considered. These hybrids would also probably change conformation extremely quickly so that an additional rate limiting process of the type

would have to be considered in the analysis. It does not seem to be within our present experimental resolution, however, to distinguish contributory reactions of this type from the simple second order reaction (2). We have presented the simplest possible scheme consistent with the data, one which may well be subject to considerable refinements. The important feature, however, is that the conversion of rapidly reacting dimer to slowly reacting tetramer occurs by processes which are usually slow compared to ligand reactions. The fast dimer is slow.

We thank Dr H. Muirhead, Professor E. Antonini and Dr M. F. Perutz for helpful discussions. This research was supported by a grant from the Science Research Council. G. L. K. thanks the Wellcome Trust for a travel grant.

Growth Rate *in vivo* of Platelet Thrombi, produced by Iontophoresis of ADP, as a Function of Mean Blood Flow Velocity

by

NICOLA BEGENT

The rate of growth of a platelet thrombus is characterized by a first order rate constant. Its measurement will be most useful in future investigations of the mechanism of platelet thrombogenesis and its reactions to drugs.

In the normal circulation, platelets have no tendency to adhere to the walls of the blood vessels, to other blood cells or to each other. When a vessel is injured in any way platelets adhere to and collect on the damaged wall with great rapidity¹. Physiologically this increase in the adhesiveness of platelets ensures normal haemostasis; pathologically it is a cause of acute thrombosis, particularly in larger arteries which are diseased but also in small arterioles which supply tissue grafts undergoing rejection².

Clearly the elucidation of the mechanism which causes this change in the platelets is interesting in itself and of great practical importance. Experiments utilizing a quantitative method for observing platelet aggregation *in vitro*^{3,4} have provided much evidence about its mechanism (for reviews see refs. 5 and 6); this can be summarized as follows. Mammalian platelets are aggregated by various agents which seem to act through the formation or release of adenosine diphosphate (ADP). The effect of ADP passes through three stages. First, the platelets rapidly change their shape from flat disks with smooth surfaces into more spherical forms with variously shaped protrusions^{7,8}; this is a consequence of a direct reaction of the platelet surface membrane with ADP and seems to require no other factors⁹. It is rapidly followed by the adhesion of platelets to each other in loose aggregates¹⁰; for this, at least, fibrinogen and calcium are also required^{11,12}. Lastly, the platelets release the contents of certain cytoplasmic granules into the plasma^{13,14}. The released material includes ADP, thereby increasing its concentration in the plasma and providing the condition for the growth of platelet aggregates through a chain reaction¹⁵. During this release reaction the aggregated platelets become much more closely packed¹⁶. The evidence so far suggests that in the loose aggregates the platelets are bound to each other by long protein or glycoprotein molecules, probably fibrinogen, and that the binding forces between these molecules and the surface of the platelets are ionic, presumably via calcium⁵.

Whether the mechanism of platelet aggregation observed *in vitro* accounts for the formation of platelet thrombi *in vivo* is unknown. It is easy to cause platelets to adhere and aggregate in living vessels by injuring them in many different ways, ranging from the macroscopic mechanical damage caused by a cut to the microscopic thermal damage caused by a laser beam. The rate at which intravascular platelet aggregates embolize from such lesions can be used to measure thrombogenic activity¹⁷

and to find out whether substances which inhibit platelet aggregation *in vitro* can do so also *in vivo*¹⁸. But analysis of the thrombogenic process requires the initiation of the increase in platelet adhesiveness *in vivo* without damage to the vessel, indeed, with the least possible disturbance to its endothelial lining, and the quantitative determination of how the initiation and growth of the platelet aggregates depends on the following variables: (1) The cellular and geometrical properties of the blood vessel at the site of the thrombogenic stimulus; (2) the nature, duration and strength of that stimulus; (3) the concentrations in the blood of other factors, that is, fibrinogen and calcium, known to be necessary for platelet aggregation *in vitro*; (4) the concentration, distribution and reactivity of platelets in the flowing blood, and (5) the properties of the blood flow, particularly its velocity.

We wish to report the first part of an investigation into

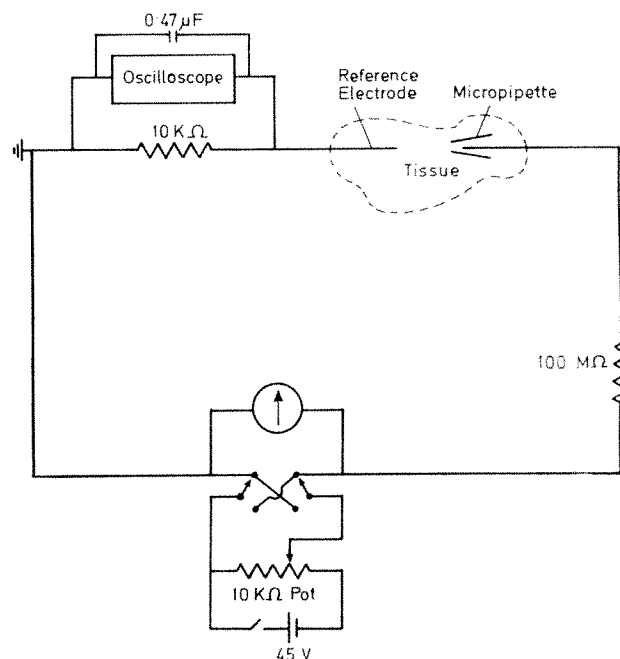

Fig. 1. Diagram of the circuit for the iontophoresis of ADP from micropipettes.

the formation of platelet thrombi or "white bodies" *in vivo* in conditions in which these variables were, as far as possible, measured or controlled, as follows. (1) The hamster cheek pouch was prepared for microscopic observation of uninjured venules of selected size. (2) The thrombogenic stimulus, ADP, was applied to the outside of the venules in minute, measured quantities by iontophoresis through micropipettes. (3) The concentrations of fibrinogen and calcium in the blood of different hamsters were assumed to be sufficiently supramaximal, as in other normal animals, not to affect the process. (4) The concentration of platelets was determined in the blood of twelve animals which were subsequently used for thrombogenic experiments. The concentrations were remarkably similar— $4.29 \pm 0.09 \times 10^8$ platelets/ml. (mean \pm s.e.m.). The reactivity of the platelets was also assumed to be similar in each animal. The quantitative distribution of the platelets in the blood stream across the venules could not yet be determined and remained unknown; possibly it could vary with changes in the velocity of the blood flow. (5) The mean velocity of the blood flow was measured in the venules by a simple technique. Results show that, in the conditions of these experiments, the rate of growth of platelet thrombi depends markedly on this velocity.

Iontophoretic Application of ADP

The application of drugs to the microcirculation by iontophoresis through micropipettes was introduced to measure the reactivity of different types of small vessels¹⁹. We used the method to apply ADP to the vessels. Micropipettes measuring 1–3 μ m across the tip were filled²⁰ with a 1×10^{-2} M solution of the sodium salt of ADP in distilled water. The solution in the micropipette was connected by an external circuit (Fig. 1) to a silver-silver chloride reference electrode. The iontophoretic movement of ADP out of the micropipettes was measured by a radioactive technique which will be described in detail elsewhere²¹. Micropipettes were filled with 10^{-2} M tritiated ADP of the highest available specific activity—44.3 Ci/mole. The tip of such a micropipette and the reference electrode were immersed in a small volume of saline. When a negative potential was applied to the pipette, radioactivity appeared in the saline and increased linearly with time for at least 20 min. With a current of 300 nA, ADP was expelled from the micropipette at a rate of about 2×10^{-14} mole/s, corresponding to about 1×10^{10} molecules ADP/s. The technique thus provided a measure

Fig. 3. Electron micrograph of the site in a venule to which ADP was applied iontophoretically by a current of 300 nA for 50 s. The lumen contains red cells (R) and a loose aggregate of platelets (Pl), some of which are adhering to an endothelial cell (E). The cytoplasm of this cell is less electron-dense than that of a neighbouring pericyte (P) and the cytoplasm of endothelial cells, not shown, at some distance from the site. A neutrophil granulocyte (NGR) lies outside the endothelial cell. ($\times 8,400$)

of the minute quantities of ADP which could be applied iontophoretically to small blood vessels and a means for controlling these quantities by varying the strength and duration of the electric current. 300 nA was the current used in the experiments to be described.

White Bodies and Thrombogenic Site

Golden hamsters of both sexes, weighing about 100 g, were anaesthetized with intraperitoneal pentobarbital (6 mg/100 g body weight). The cheek pouch was everted and spread on a special 'Perspex' stage (see Fig. 1 from ref. 19). The top layer and fine connective tissue were removed and a Leitz Laborlux microscope (mostly with a $\times 20$ objective and a $\times 10$ eyepiece) was focused on the thin lower layer which was transilluminated from below with light from a xenon lamp. The preparation was bathed continuously in an aerated saline solution (composition in mM: NaCl 131, KCl 4.0, CaCl_2 3.0, MgSO_4 1.0, glucose 10 and Tris 5.0; pH 7.4), and maintained accurately at 37°C. The preparation remained in good condition, as assessed by the blood flow in and the reactivity of the vessels and by the absence of oedema, for at least 2–3 h.

A micropipette filled with ADP solution was manipulated closely against the outside of a small venule (diameter 40–70 μ m). The reference electrode was immersed in the bathing solution. When a negative potential was applied to the micropipette to eject ADP, the diameter of the venule was unaltered (Fig. 2). The application of ADP for more than 5 s caused the formation of a white body attached to the inside of the venule beneath or slightly downstream from the tip of the pipette (Fig. 2). A similar application of ADP to an arteriole caused it to constrict. White bodies formed in most arterioles but in all venules; for this reason venules were chosen for making measurements on the growth of white bodies. The iontophoretic application of nucleotides closely related to ADP, including AMP and GDP at similar

Fig. 2. Normal venule before (left) and after (right) the application of a negative potential to the microelectrode shown which was filled with 10^{-2} M ADP. The iontophoretic current was 150 nA. The photograph on the right was taken when the white body had grown for 50 s. Scale, 100 μ m.

Fig. 4. Growing white body produced by the iontophoretic application of ADP to a venule. The white body appears as a segment of a circle. Below is a diagram showing the measurements made for calculating the volume of the white body by the formula.

concentrations, did not produce white bodies in the venules, nor did inorganic phosphate or saline. The effect of ATP, which *in vitro* inhibits the aggregating effect of ADP (ref. 4), was variable, presumably because of breakdown to ADP. These results indicated that the white body-producing effect was specific for ADP.

The next problem was to establish whether the site where the iontophoretic application of ADP caused white bodies to form was normal or abnormal, and, if so, to find some measure of the abnormality. Cortical blood vessels of anaesthetized rabbits can be injured so slightly that no white bodies form in them unless ADP is also applied²², and this suggests that the formation of white bodies depends on the additive effects of mechanical injury and ADP. In our

experiments it was possible that the dissection of the pouch and/or the iontophoretic current could have caused sufficient injury to the venules for ADP to have a similar additive effect. To assess this, serial electron micrographs were made of the sites to which either ADP, or GDP as a non-thrombogenic control substance, had been applied iontophoretically; the preparations were immediately fixed in glutaraldehyde followed by osmic acid²³. The pictures showed that the plasma membrane of the endothelial cells and the junctions between them were intact and apparently normal; the only abnormality was some loss of electron density of the endothelial cytoplasm compared with that of cells in control areas (Fig. 3). This abnormality occurred, however, with both ADP and GDP and was therefore not associated specifically with the thrombogenic action of ADP. The cause of the abnormality is still uncertain.

White bodies have been produced by damaging small blood vessels electrically²⁴⁻²⁶; however, the currents required for this were up to 300 μ A rather than 300 nA, that is, a thousand times greater than the iontophoretic current used in our experiments. Furthermore, any heat produced would, in the conditions of these experiments, be rapidly dissipated by the superfusing saline as well as by the blood stream in the vessels. It was concluded that the iontophoretic applications of ADP as described did not cause any clear or specific abnormality to the vascular endothelium but that some mild, unspecific change did occur inside the cells; this has to be further investigated.

Growth of White Bodies

With continuing passage of the iontophoretic current each white body continued to grow for about 1 min. Thereafter, the white bodies embolized in whole or in part and new ones continued to form and embolize at the same site until the current was switched off. The rate of growth of white bodies was determined by filming the site where ADP was applied at 32 f.p.s. for 2 s every 5 or 10 s until the white body embolized. As long as the white bodies remained small relative to the diameter of the venules, their outline in the lumen approximated to a segment of a circle (Fig. 4). The base ($2a$) and height (h) of each growing white body after increasing time were measured on the film. On the assumption that the shape of the white body approximated to a segment of a sphere

Fig. 5. Increases in surface area (■) and volume (○) of a white body with time. On the right, the increase in volume is plotted semi-logarithmically against time, showing the line of best fit.

(radius r), its volume (V) and surface area (A) were calculated by $A = 2\pi rh$ and $V = \frac{1}{3}\pi h(h^2 + 3a^2)$. Clearly this assumption was only a reasonable approximation; for one thing, it neglected the effect of the curvature of the vessel wall. This source of error was minimized by using for the measurements only white bodies with heights less than one-third of the vessel diameter.

The surface area of the white bodies increased linearly with time while the volume increased exponentially (Fig. 5). Therefore a semi-logarithmic plot of volume against time provided a rate constant of the growth of the white body, which itself provided a measure of the growth rate and a means for determining the effect of the different variables on it.

Growth of White Bodies depends on Blood Flow

The mean blood flow velocity in venules in which white bodies were produced was measured by a new, simple technique. A white body was produced in the usual way about 500 μm upstream from the site where the growth rate of another white body had just been determined. When the upstream white body was still small but clearly visible, the iontophoretic current was switched off; within

Fig. 6. Serial photomicrographs, at intervals of $1/16$ s, of two white bodies passing along the same venule. The white body on the left moved at $625 \mu\text{m/s}$ and that on the right at $655 \mu\text{m/s}$. Scales, $100 \mu\text{m}$.

Fig. 7. Effect of mean blood flow velocity in venules on the growth rate constant (s^{-1}) of white bodies: results from seventeen experiments. Diameter of the venules: \circ , 49–49 μm ; \bullet , 50–59 μm ; \bullet , 60–69 μm ; \bullet , > 70 μm .

a few seconds the white body embolized. With the microscope focused on the downstream site, the embolus was filmed at 32 f.p.s. as it was swept along by the blood stream. The film was used for measuring the velocity at which the white body moved. An example is shown in Fig. 6: the velocities of two different white bodies were measured in the same vessel, with very similar results—625 and 655 $\mu\text{m/s}$. In three other such experiments, the velocities of different white bodies in the same vessel were equally similar although carried at different distances from the vessel wall. The results of blood flow velocity measurements made in this way were also very similar to measurements made in such venules in the hamster cheek pouch with a particle velocity meter²⁷.

In seventeen experiments, measurements were made of both mean blood flow velocity and the growth rate constant of white bodies, produced in venules of similar size by iontophoretic currents of 300 nA (Fig. 7). The growth rate of white bodies increased with increasing mean blood flow velocity up to a sharp maximum at velocities of 300–400 $\mu\text{m/s}$. With higher velocities the growth rate decreased and remained approximately constant, at about half the maximum, as the mean flow velocities increased from about 600 to about 2,500 $\mu\text{m/s}$. With velocities greater than 3,000 $\mu\text{m/s}$, no white bodies formed.

The causes of this relationship have not yet been established. It is reasonable to suggest, however, that the rate of growth of white bodies in the conditions described was determined by at least two opposing factors—the rate at which platelets were brought to the site and the rate of shear which would tend to prevent platelets from adhering. Both factors depend on blood flow velocity. Our observations suggest that when the mean blood flow velocity was less than about 400 $\mu\text{m/s}$, the increasing growth rate of the white body was a result of the increasing rate of supply of platelets which were able to adhere and that, at higher flow velocities, shear increased to such an extent that it prevented more platelets from adhering.

This interpretation is based on assumptions the validity of which still has to be determined. First, it is assumed that the velocity profile in the venules was not parabolic but rather flat, almost to the walls, so that measurements of blood flow velocity indeed represented mean velocity. The initiation of white bodies presumably depends primarily on the concentration and the movement of platelets in immediate proximity to the vessel wall, where flow velocity is known to be slow. As a white body grows

into the lumen, the mean blood flow velocity past it must increase if the pressure remains constant, and this local increase in flow velocity presumably also affects the process. To investigate these flow effects we are now measuring velocities of blood cells flowing along the vessel wall by means of high speed cinematography.

Another assumption is that when platelets make contact with the thrombogenic vessel wall or with other platelets in the growing white body, the time of contact is long enough, whatever the rates of flow and shear, for the change in platelet shape to occur which is a prerequisite for aggregation by ADP *in vitro*⁹. It will be necessary to find means of measuring contact times at different shear rates.

Finally, the demonstration that the growth rate of a platelet thrombus is characterized by a first order rate constant will be very useful in the further investigation of the mechanism of platelet thrombogenesis and in measuring the *in vivo* effectiveness of drugs capable of inhibiting platelet aggregation *in vitro*.

We thank Mr Brian Sheppard for help with the electron microscopy.

Geomagnetic Polarity Change, Volcanic Maxima and Faunal Extinction in the South Pacific

by

J. P. KENNETT

N. D. WATKINS

Graduate School of Oceanography,
University of Rhode Island,
Kingston, Rhode Island 02881

Studies of deep-sea sedimentary cores from Antarctic Pacific waters show that some volcanic maxima occurred when the geomagnetic polarity was changing. Upper mantle activity and geomagnetic polarity change may therefore be related. Coincidences of faunal extinction and geomagnetic polarity change may be explained by corresponding volcanically induced climatic changes.

GEOMAGNETIC field reversals occurred more than twenty times during the past 4 m.y. (ref. 1) and probably more than one hundred times during the Tertiary². The most significant aspect of this discovery is the recognition of important features of the history of geomagnetic polarity¹ in the linear magnetic anomalies of the oceanic crust^{3,4}, and their convincing interpretation in terms of sea-floor spreading⁵⁻⁸.

The geomagnetic polarity history has also been recognized in deep-sea sedimentary cores^{9,10}. In such studies, several microfaunal extinctions and appearances have been recognized as synchronous, and virtually simultaneous with the period of transition between opposite geomagnetic polarities⁹⁻¹³ which lasts about 5,000 years¹⁴. The reasons for these extinctions and appearances are unknown, but they may be the result of climatic change and polarity change being related^{15,16}, or of increased mutation rates during polarity changes¹⁷, although several authors^{15,18,19} oppose this possibility.

Heirtzler²⁰ has recently speculated on a relationship between earthquake activity (and by implication upper mantle activity) and geomagnetic polarity change. He reasons that because there is evidence to show that earthquakes of magnitude 7.5 or greater may cause wobble of the spin axis²¹, it is therefore conceivable that an Earth wobble may be of a magnitude sufficient also to cause reversal of the geomagnetic field. Here we present data pertinent to Heirtzler's speculations²⁰, and we expand such speculations to include our preferred explanation of the synchronous geomagnetic polarity changes and faunal extinctions.

We know of no method to detect the time of occurrence and frequency of large earthquakes in the geological past. Stress release is often manifested in volcanic activity, however, so a search may be profitably made for evidence of relationships between volcanic maxima and geomagnetic polarity change. Volcanism certainly may have more than one cause, and on a global scale must be virtually continuous, so we therefore emphasize our use of the term "volcanic maxima". If relationships exist between polarity change and upper mantle activity they are more likely to be found in oceanic areas, for there the mantle is most mobile and accessible, and (in all probability) more commonly at "threshold", in terms of potential volcanism. Our search therefore examines the character of volcanic activity during polarity change in some deep-sea sedimentary cores.

The cores used were collected during cruises of USNS Eltanin and their locations are included in Fig. 1 and Table 1. Core selection was based only on length, minimum age, and geographic position. Collection, transportation, and sampling procedures have been described elsewhere²². In this study, specimens for palaeomagnetic study were taken at 10 cm intervals, demagnetized at 150 oersteds using a four axis tumbler²³ and measured using a 5 Hz spinner magnetometer²⁴.

At 20 to 30 cm intervals the palaeomagnetic specimens were then weighed dry, disaggregated and washed on a 63 μ m mesh Tyler screen. The sand-size fraction was examined to determine the relative abundance of volcanic glass shards and the nature of the micro-fossils. Restriction to the sand-sized fraction probably eliminates much

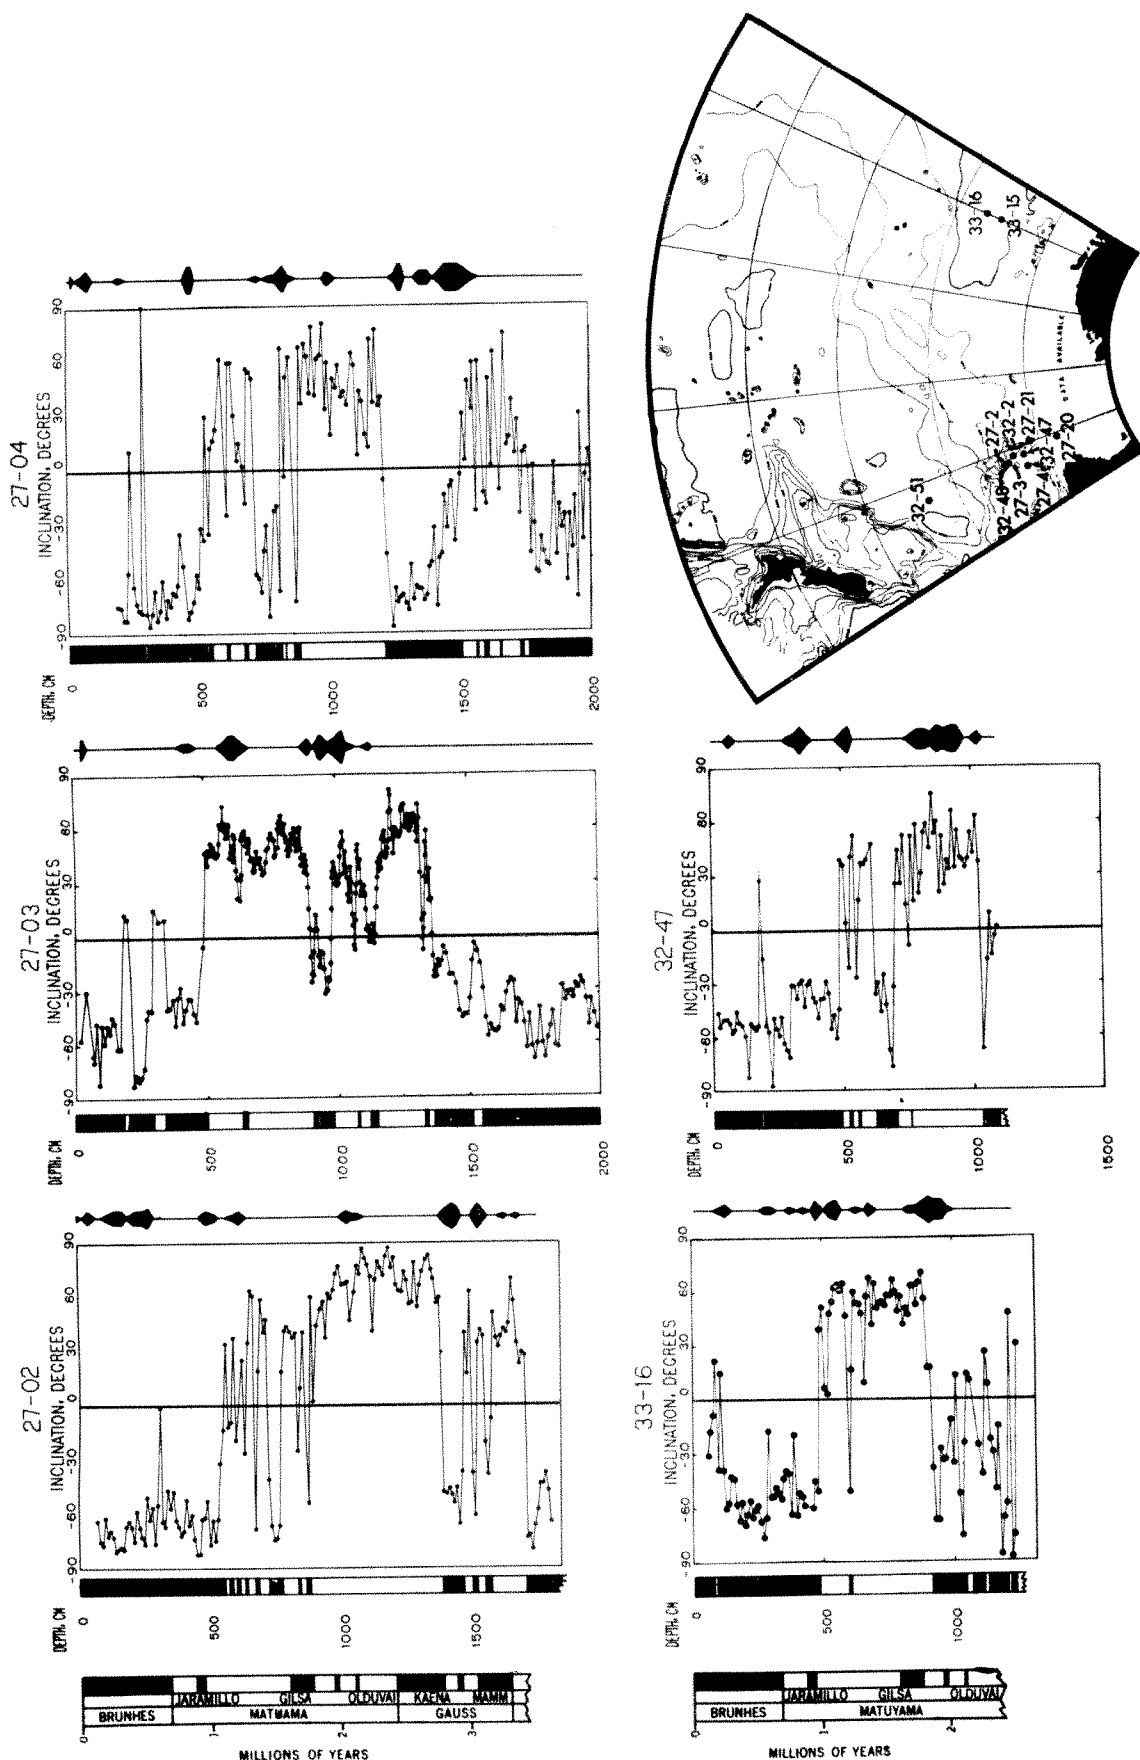

Fig. 1. Inclination of natural remanent magnetism, and fraction of sand-sized ash in five selected cores. Location of these and other cores (examined in Fig. 2) is given in the inset, and in Table 1 (core number at head of each plot). In each core, the inclination of natural remanent magnetism is shown for each specimen. Negative inclination (above horizontal) is normal polarity. Inclination without sign is positive (below horizontal) or reversed polarity. Depth of specimen in core shown next to each plot, where a polarity log is also shown; this is a non-subjective plot of the inclination data, with black = normal polarity; clear = reversed polarity. The polarity time scale at the left of each plot, from left to right, of the age in m.y.; the names of the polarity epochs; the names of the polarity events; and the polarity history. The histogram to the right of each log expresses the fraction of sand-sized volcanic glass shards and other volcanic material in the given specimen. It results from examination using a binocular microscope and is defined using micropaleontological conventions. The x-axis definition is five-fold as follows: width 4 (width) = very abundant; 3 = abundant; 2 = common; 1 = uncommon; 0 (fine line) = very rare or absent. Note that the inclination plot of core 27-03 includes a sequence of data from specimens taken at 2 cm intervals for a special study of the Matuyama epoch polarity history and subjected to a five-point running average. The corresponding polarity log is a slightly subjective interpretation of these data.

Table 1. DETAILS OF CORE LOCATION AND STATISTICAL ANALYSIS OF THE RELATIONSHIP BETWEEN MAGNETIC POLARITY BOUNDARIES AND VOLCANIC ASH HORIZONS

Core No.	Latitude (degrees south)	Longitude (degrees east)	Water depth (m)	Core length (m)	Percentage ash (<i>Pa</i>)	No. of reversals	No. of coincidences	<i>Pa.g</i>
E27-02	63° 00'	177° 42'	3,358	16.97	42.6	8	4	0.469
E27-03	66° 04'	176° 30'	3,520	21.66	34.1	8	6	0.023
E27-04	68° 03'	174° 35'	3,433	19.89	37.3	8	5	0.137
E27-20	71° 57'	178° 36'	2,116	5.20	—	—	—	—
E27-21	69° 02'	179° 50'	3,440	16.07	34.1	8	3	0.572
E32-02	67° 22'	178° 44'	3,656	10.21	67.1	3	3	0.303
E32-47	68° 06'	176° 10'	3,413	10.93	45.4	5	5	0.019
E32-51	58° 50'	176° 52'	4,845	7.53	—	—	—	—
E33-15	65° 07'	199° 45'	4,823	11.52	21.6	8	5	0.158
E33-16	63° 14'	199° 59'	4,890	15.03	67.3	8	6	0.489

Percentage ash is based on Fig. 1: it is the fraction of the core in which any sand-sized ash is found, and is not a relative volume count. It follows that this is also the probability (*Pa*) of finding sand-sized ash in any part of each core. Number of reversals is the number of known polarity changes during the last 2.5 m.y., or less if the given core does not reach that age. Number of coincidences is the number of times that an ash occurrence is found at a polarity change in Fig. 2. A ± 30 cm range is allowed for detection of such coincidences, because reworking and polarity recording imperfections are likely to be present. *Pa.g* is the probability that the observed number of coincidences of ash and geomagnetic polarity change are simply the result of coincidence of two randomly occurring phenomena. No analysis is given for E32-51: this is illustrated in Fig. 2 (right) and is not amenable to analyses.

very fine volcanic material, which simplifies the search for evidence of regional volcanic maxima.

Sediment type in the cores varies greatly. It includes lutite, silicious and carbonate ooze, and glacial-marine material. Most cores lack planktonic foraminifera, because of their solution at the depth of the cores, but when present they are restricted to one species, *Globigerina pachyderma*. Radiolaria are much more diverse, and are often abundant throughout the cores, and frequently offer the only micropalaeontological control possible.

The palaeomagnetic results are shown in part in Fig. 1 and completely in Fig. 2. Material as old as the Gilbert Epoch is identified. The correlation lines for the major polarity (epoch) boundaries have been readily confirmed by applying the radiolarian zonation established by Opdyke *et al.*⁹ and Hays and Opdyke¹³. The species which were particularly valuable in our correlations were *Prunopyle titan* and *Desmospyris spongiosa* (the extinction of which coincides approximately with the Gauss-Matuyama boundary); and (in northern cores) *Eucyrti-*

dium calvertense whose extinction is, we believe, associated with the Gilsa event¹ and *Saturnulus planetes*, which disappeared near the Brunhes-Matuyama boundary (0.7 m.y.). Correlation of the shorter duration magnetic polarity events is shown in Fig. 2 only for the events in the Matuyama epoch. Palaeontological controls for these are simply not available locally, and the correlations are therefore made subjectively using the magnetic data alone and, where these are not clear, by extrapolation of sedimentation rates. Question marks are added, where appropriate, to Fig. 2.

Volcanic shards, which usually do not form megascopically distinct layers, were found in all the sedimentary cores examined for this study. Within each core large variations in the relative abundance of the shards occur, ranging from complete dominance to virtual absence (Figs. 1 and 2). The glass shards occur mostly as flaky fragments, very similar to those illustrated by Ninkovitch^{25,26}. The data clearly show periods of volcanic maxima. A general increase in the size of the glass shards, and in the amount of other volcanic debris, such as small volcanic pellets, occurs in cores nearer the Balleny Islands, suggesting that the source is at least in part in this vicinity. Similar but finer volcanic glass is found at the same palaeomagnetic horizon in the central Pacific (core E33-16, Fig. 1) strongly suggesting either contemporaneous activity in the area, or (more likely) a very large fallout area, possibly larger than previous considerations allow²⁷.

Figs. 1 and 2 clearly show that when geomagnetic polarity changes were taking place, volcanic maxima were also occurring, at least locally. Volcanic fragments are most abundant and consistent in their occurrence close to the Brunhes-Matuyama boundary (0.7 m.y.), near the Matuyama-Gauss boundary (2.4 m.y.), and during at least two periods within the Brunhes epoch (0 to 0.7 m.y.). Other less well defined horizons are related in part to the sediments of the shorter duration events, and the Gauss-Gilbert boundary. Volcanism was clearly taking place locally during other periods. It is intriguing that the Brunhes-Matuyama and Matuyama-Gauss polarity changes are remote from evidence of

Fig. 2. Histograms of volcanic material fraction in each core and the geomagnetic correlation lines. For description of the volcanic fraction histogram construction see legend to Fig. 1. Geomagnetic polarity time scale after Cox¹ as in Fig. 1. The correlations at the three magnetic epoch boundaries are given by heavy dashed lines. These are confirmed micropalaeontologically. The correlations of the polarity events within the Matuyama epoch are based on magnetic and sedimentation rate data only. Core 32-51 features a major discontinuity, which results in most of the upper 2.4 m.y. of the core being absent.

volcanic activity in only one of the fourteen such examples contained in the eight cores shown in Fig. 2 (left). Nevertheless, we obviously cannot dismiss the possibility that the results are simple coincidence. Despite obvious experimental and analytical difficulties, we therefore offer a statistical analysis (Table 1). Our approach is to restrict analysis to sediments aged 2.5 m.y. or less if the cores do not reach this age, as is the case in E32-02 and E32-47. We assume that eight polarity changes have taken place: one each for the Brunhes-Matuyama and Matuyama-Gauss boundaries and two each for the three known events in the Matuyama. Counting the percentage of the core in which any ash is observed (Fig. 2) provides the probability (Pa) of ash occurring in any part of the core. Combined with the number (N) of observed coincidences of ash and polarity change (Fig. 2 and Table 1) we can then express the probability ($Pa.g$) of the observed occurrences of simultaneous polarity change and ash deposition being a simple coincidence of two independent variables. Other statistical approaches are possible.

In cores E27-03 and E32-47 there is only a 0.02 probability that the ash and polarity change coincidences occur by chance only (Table 1). In cores E27-04 and E33-15 the probability is less than 0.16; but this rises to 0.30 in E32-02, where the ash content is very high. In cores E27-02 and E33-16, fewer coincidences and high ash content, respectively, reduce $Pa.g$ to almost even chance. Only in core 27-21 is $Pa.g$ greater than 0.50, meaning that in this core there is a better than even chance that the three observed coincidences of polarity change and ash are random events.

Fig. 2 (right) contains the results from one other core. E32-51 contains a disconformity, which has resulted in only a few centimetres of Brunhes sediment being above the oldest Matuyama, and what appears to be a complete Gauss section. Micropalaeontological evidence confirms these correlation lines. Both the Kaena and Mammoth events are clearly displayed: no additional events in the Gauss are indicated. Volcanic materials are at a maxima very close to these events and limits of the Gauss epoch.

Palaeomagnetic and potassium-argon analyses of lavas on Nunivak Island²⁸ (Fig. 3a) show that volcanic maxima on the island are most marked close to the geomagnetic polarity reversals defined. McDougall and Chamalaun's²⁹ results from the Indian Ocean islands of Mauritius, Réunion, and Rodriguez (Fig. 3b) show frequent volcanism during the Brunhes epoch and there may be a correlation between volcanic activity and polarity change during the preceding 3 m.y. A coincidence of ash layers and geomagnetic polarity change is included in the results of Ninkovitch²⁵ from study of a series of cores taken from east of New Zealand (Fig. 3c). Here five megascopically distinct tephra are reported. One is closely associated with the polarity change at the end of the Jaramillo event, two straddle the Brunhes-Matuyama polarity change, and two occur within the Brunhes. Similarly, Ninkovitch *et al.*³⁰ report megascopic ash layers in the North Pacific (core F20-119) which coincide with the Jaramillo event (Fig. 3d) and Genter *et al.*³¹ report an ash layer in the north-east Indian Ocean (core V19-153) which coincides with the Brunhes-Matuyama boundary. While we find these observed correlations of volcanism and polarity change difficult to accept as purely coincidental, we stress our awareness of the fact that many more data are required to prove that the implied relationship is meaningful.

We now briefly examine the relevance of our data to problems of climatic changes and microfaunal extinctions and appearances. If significant widespread increases in volcanism have occurred during restricted intervals of geological time, then climatic changes are very likely, particularly at high latitudes, because volcanic ash, which remains in the atmosphere for prolonged intervals of time and moves poleward at high altitudes, inhibits solar radiation at the surface^{32,33}. In this context it is therefore

possibly significant that a distinct world-wide cooling occurred near the Brunhes-Matuyama boundary^{13,34,36}, and that other climatic coolings may be associated with the Gilsa event and Matuyama-Gauss boundary³⁷. Increases in volcanism within the Brunhes epoch as indicated by us in the Southern Oceans occur in New Zealand (personal communication from H. W. Wellman). This coincides with, and may be related to, the much greater climatic fluctuation of the past 0.7 m.y., compared with the preceding million years^{34,36,38,39}.

Of eight observed microfaunal extinctions and appearances in the Southern Ocean, six occur either during or very close to geomagnetic polarity changes⁴⁰. We suggest that the climatic changes which can result from volcanic maxima are much more plausibly the cause of such extinctions and appearances than increased radiation at the water surface during any dipole collapse accompanying a polarity change, although other explanations must be considered.

We conclude that our results provide sufficient evidence to justify serious consideration of Heirtzler's²⁰ speculations of a connexion between geomagnetic polarity change and upper mantle activity, which was also proposed by Hide⁴¹. Volcanic maxima during polarity changes may be expected to have an influence on climatic conditions, particularly at very high latitudes, and may therefore also be the indirect cause of those microfaunal extinctions which have occurred during geomagnetic polarity changes.

The work is supported by US National Science Foundation grants and by a grant from the Florida State University who also provided computer time.

The Non-existence of Stationary Infinite Newtonian Universes and a Multi-dimensional Model of Shot Noise

HOLTSMARK¹, in an electrostatic context, and Chandrasekhar², in the case of a Newtonian gravitational field, have given a simple model which describes the electrostatic or gravitational field at an arbitrary point in space. They take the point as the origin of coordinates and calculate the field there due to point charges or masses which are scattered randomly and homogeneously throughout the space. Specifically, the field is

$$\mathbf{X}_R(0) = K \sum_{j=1}^N \mathbf{t}_j / |\mathbf{t}_j|^3 \quad (1)$$

where K is a proportionality constant, and in a sphere of radius R it is supposed that there are N points scattered randomly and located at $\mathbf{t}_1, \dots, \mathbf{t}_N$. By letting N and $R \rightarrow \infty$ in such a way that the density of points $3N/4\pi R^3 \rightarrow \lambda$, Holtsmark showed that the probability distribution of $\mathbf{X}_R(0)$ converges to a limit, being the distribution of $\mathbf{X}^p(0)$, say.

Now, if this model is to be at all realistic, it must have the property of stationarity. That is, if our point is taken not at the origin (which for equation (1) is the centre of the sphere R) but at \mathbf{t} , say, then by starting from

$$\mathbf{X}_R(\mathbf{t}) = K \sum_{j=1}^N (\mathbf{t}_j - \mathbf{t}) / |\mathbf{t}_j - \mathbf{t}|^3 \quad (2)$$

and proceeding to the limit with R and $N \rightarrow \infty$ as before, then the resulting distribution, of $\mathbf{X}^p(\mathbf{t})$, say, should be the same as for $\mathbf{X}^p(0)$. A mathematical analysis to be given elsewhere³ shows that this is not so; hence the non-existence statement in the title.

The point of this conclusion, which may at first sight seem to be a piece of mathematical pedantry, is more apparent when we consider simultaneously³ the field at two points separated by a distance $2\mathbf{t}$. The limiting distributions obtained by taking the limit R and $N \rightarrow \infty$ as before in the two possible definitions (equations (3) and (4) below) are different, yet comparison with equations (1) and (2) gives no reason for preferring either definition.

$$(\mathbf{X}_R(0), \mathbf{X}_R(2\mathbf{t})) = K \sum_{j=1}^N (\mathbf{t}_j / |\mathbf{t}_j|^3, (\mathbf{t}_j - 2\mathbf{t}) / |\mathbf{t}_j - 2\mathbf{t}|^3) \quad (3)$$

$$(\mathbf{X}_R(-\mathbf{t}), \mathbf{X}_R(\mathbf{t})) = K \sum_{j=1}^N ((\mathbf{t}_j + \mathbf{t}) / |\mathbf{t}_j + \mathbf{t}|^3, (\mathbf{t}_j - \mathbf{t}) / |\mathbf{t}_j - \mathbf{t}|^3) \quad (4)$$

The model here is a special case of a generalization of shot noise in which points are scattered homogeneously and randomly (as a Poisson process) in an n -dimensional Euclidean space with density λ , with any point \mathbf{t}_j contributing the disturbance $\mathbf{f}(\mathbf{t}_j - \mathbf{t})$ to the total disturbance (summed over j)

$$\mathbf{Y}(\mathbf{t}) = \sum \mathbf{f}(\mathbf{t}_j - \mathbf{t}) \quad (5)$$

at any point \mathbf{t} . [In equations (1) and (2), $n=3$ and $\mathbf{f}(\mathbf{t}) = K\mathbf{t}/|\mathbf{t}|^3$. If instead the Yukawa⁴ disturbance function $\mathbf{f}(\mathbf{t}) = K\mathbf{e}^{-at}(1 + at)\mathbf{t}/t^3$, where $t = |\mathbf{t}|$, is used, then the distributions of $\mathbf{X}^p(\mathbf{t})$ and $\mathbf{X}^p(0)$ are the same.] The existence of the limiting distributions for $\mathbf{X}^p(\mathbf{t})$ and $\mathbf{Y}(\mathbf{t})$ depends on the behaviour of $\mathbf{f}(\mathbf{t})$ for large $|\mathbf{t}|$, and possibly also (as with equation (1)) on the order of summation of

the points \mathbf{t}_j in equation (5). Assuming that $\mathbf{f}(\mathbf{t})$ is radially symmetric so that $\mathbf{f}(\mathbf{t}) = g(t)\mathbf{t}/t$ for $t = |\mathbf{t}|$ and some function $g(t) \geq 0$ with $g(t) \downarrow 0$ for sufficiently large $t \rightarrow \infty$, the sum for equation (5) is well defined and finite for all \mathbf{t} when, for sufficiently large a ,

$$\int_a^\infty t^{n-1} g(t) dt < \infty \quad (6)$$

Sums analogous to equations (1) and (2), that is,

$$\mathbf{Y}_R(\mathbf{t}) = \sum_{|\mathbf{t}_j| \leq R} \mathbf{f}(\mathbf{t}_j - \mathbf{t}) \quad (7)$$

have probability distributions with a limit for $\mathbf{t} = 0$ when

$$\int_a^\infty t^{n-1} g^2(t) dt < \infty \quad (8)$$

and there is a limit for all \mathbf{t} when, additionally,

$$\int_R^{R+a} t^{n-1} g(t) dt \quad (9)$$

has a finite limit as $R \rightarrow \infty$. These limiting distributions coincide for all \mathbf{t} when the limit of the integral (9) is zero.

I thank Professor Allan H. Marcus of Johns Hopkins University for discussion and access to unpublished material.

Giorgi System

THE letter by Stopes-Roe¹ on "Essential Features of the Giorgi System of Electromagnetism and a Basic Error by Sommerfeld" reveals that a bewildering number of formulations of the equations of electromagnetism are being advocated. Some related problems are discussed by Rosser².

In SI units the constant $\mu_0 = 4\pi \times 10^{-7}$ is indispensable in many formulae, if the dimensions are to balance and the correct numerical values are to be obtained. The difficulty arises from attributing to this constant the physical properties of permeability. As shown by Stopes-Roe, different definitions of magnetic moment lead to different versions of magnetic formulae; these definitions with their associated formulae are self-consistent and all equally correct in free space. If, however, μ_0 in the free space formulae is replaced by $\mu_0\mu_r$ in a medium of relative permeability, μ_r , the different systems predict different results. In particular the Kennelly formulation predicts that the field H due to a magnetic dipole is inversely proportional to μ_r , while the Sommerfeld formulation predicts that it is independent of μ_r .

I have so far failed to find references to any experimental evidence that would distinguish between these predictions. Because the experiments would have to use a fluid with μ_r very close to unity the experiments would be difficult, although probably not impossible.

Many older textbooks, such as Starling³, deduce from a dubious analogy with electrostatics that H is inversely proportional to μ_r . The electrostatic proof rests on the Gauss theorem in the form that the integral of the outward normal displacement D_n over a closed surface

$$\int_s D_n ds = 4\pi q \quad (1)$$

Fig. 1. Polarization and demagnetizing field in ellipsoid.

where q is the charge enclosed in e.s.u. This proof is inapplicable to magnetism because the equivalent formula is

$$\int_s B_n ds = 0 \quad (2)$$

Page and Adams⁴ deduce that the field outside a long thin magnet with approximately point poles is inversely proportional to μ_r , but from the nature of the approximations it is unlikely that this result holds for other shapes of magnet.

An illuminating example is provided by an ellipsoid with uniform polarization J in the X direction, as shown in Fig. 1. There is then a uniform demagnetizing field H_d inside the ellipsoid and using the Kennelly convention

$$B = J - \mu_0 H_d \quad (3)$$

The field H at any external point and the demagnetizing field H_d inside the ellipsoid can be calculated by integrating contributions from dipoles in small elements of volume throughout the ellipsoid, although sometimes the mathematics is simplified by using an equivalent distribution of poles on elements of surface of the ellipsoid. Whether the field is being calculated inside or outside the ellipsoid, the correct result is given by the free space formula independently of the relative permeability of the ellipsoid.

Now the Kennelly formulation requires that the field due to a point pole or dipole is inversely proportional to μ_r , when the ellipsoid is immersed in a medium. As a constant, $1/\mu_r$ can be taken outside the integral and therefore applies to the whole ellipsoid. Thus at any point outside the ellipsoid H is reduced by $1/\mu_r$ and $B = \mu_0 \mu_r H$ is unchanged. In particular this is true for an axial point a and an equatorial point b . Now at an equatorial point b , H is tangential to the surface of the ellipsoid and is therefore continuous across the boundary. So H_d is also reduced by the factor $1/\mu_r$. Inside the ellipsoid H_d is uniform, so H_d is also reduced by the factor $1/\mu_r$ at the axial point a just inside the ellipsoid. From equation (3), therefore, if J is unchanged, as is certainly possible in a hard magnetic material, B is increased by $H_d(1 - 1/\mu_r)$. Because B is normal to the surface of the ellipsoid at a and is continuous across the boundary, B is also increased outside the ellipsoid at a . Hence using the Kennelly formulation and the continuity relations, two contradictory results have been deduced. Outside the ellipsoid at an axial point a : (i) B is unchanged by a medium; (ii) B is increased by a medium. A similar reduction *ad absurdum* can be applied to the Sommerfeld convention.

The conclusion seems to be that we should not expect to find that the B and H produced by a magnet in a medium are simple functions of μ_r . They are more probably complicated functions of μ_r and geometrical factors depending on the shape of the magnet.

When a magnet is placed in a medium new dipoles are induced in the medium and those inside the magnet may or may not be altered. In general B and H can be calculated by taking account of all the macroscopic currents and magnetic dipoles that are near enough to be effective, using only the free space formulae.

This process would often be complicated, but the use of a formula involving μ_r or $1/\mu_r$ only as a simple coefficient is justified only when it leads to the same result. For the purpose of calculating B , H or magnetic forces (although not, of course, for some phenomena such as gyromagnetism), it does not matter whether magnetic dipoles are

spinning electrons or orbiting electrons. It is entirely a matter of mathematical convenience whether we treat them as dipoles or small current loops.

We may not, however, replace a magnet by a single solenoid, when we are considering conditions inside the magnet. These depend on the magnet consisting of many interacting dipoles or current loops. This interaction is lost if we postulate a single solenoid to represent the magnet.

In conclusion, an explanation of the physical difference between B and H in a magnetic material may be of interest. The flux density B is measured by a coil encompassing the material and in general is due to three causes: (i) external causes, such as a current in a solenoid surrounding the material. (ii) The self-demagnetizing field originating from discontinuities at the boundaries of the material. (iii) The local polarization J .

The field H is that which influences J by altering the orientation of the individual dipoles or current loops. An individual dipole or current loop can exert no torque upon itself, so that J does not contribute to H and

$$H = (B - J)/\mu_0 \quad (4)$$

I have constructed a model (yet to be published) consisting of a cubic array of small parallel magnets representing the atomic dipoles in a material. If one of these magnets is free to rotate, it turns so that it points in the opposite direction to the flux produced by the array as a whole, that is in the direction of H not B .

Scattering of Gravitational Radiation by a Schwarzschild Black-hole

THE discovery of pulsars and the general conviction that they are neutron stars resulting from gravitational collapse have strengthened the belief in the possible presence of Schwarzschild black-holes—or Schwarzschild horizons—in nature, the latter being the ultimate stage in the progressive spherical collapse of a massive star. The stability of these objects, which has been discussed in a recent report¹, ensures their continued existence after formation. Inasmuch as the infinite redshift associated with it and its behaviour as a one-way membrane make the

Fig. 1. The effective potential V_{eff} for the odd-parity gravitational waves of the lowest mode $l=2$ plotted against x^* .

Schwarzschild horizon at once elusive and intriguing, it is important to explore theoretically all possible modes in which the presence of such a black-hole manifests itself. In what follows, we present a partial summary of some results obtained from an investigation of the scattering of gravitational waves by a Schwarzschild horizon.

To begin with, a spherically symmetric mass distribution is assumed to have collapsed into its Schwarzschild surface in the infinitely remote past. The scattering of gravitational waves by this configuration can be examined employing the perturbation techniques developed by Regge and Wheeler². Retaining the notation of the authors and concentrating on the odd-parity waves, the perturbed Schwarzschild exterior line element in the Regge-Wheeler canonical gauge can be written as

$$ds^2 = -(1 - 2m/r)dt^2 + (1 - 2m/r)^{-1}dr^2 + r^2(d\theta^2 + \sin^2\theta d\varphi^2) \\ + (h_0(r) dt d\varphi + h_1(r) dr d\varphi) \exp(-i\omega t) \sin\theta \frac{dP}{d\theta} l(\cos\theta)$$

where ω is the frequency of the gravitational waves. The Einstein empty-space field equations computed to first order in the perturbations³ yield the following differential equations for the radial functions h_0 and h_1

$$\frac{d^2 Q}{dx^{*2}} + (k^2 - V_{\text{eff}})Q = 0 \text{ with } V_{\text{eff}} = \\ (1 - 1/x) (l(l+1)/x^2 - 3/x^3)$$

and

$$h_1 = \frac{i}{k} \frac{d}{dx^*} (xQ)$$

where we have defined

$$x = r/2m, \quad x^* = x + \ln(x-1), \quad k = 2m\omega, \quad \text{and} \quad Q = (1 - 1/x)h_1/x$$

The exterior from $r = 2m$ to ∞ corresponds to the range of x^* from $-\infty$ to $+\infty$. The motion of the gravitational waves in this space is governed by the effective potential V_{eff} produced by the collapsed mass. The effective potential for the lowest possible mode $l=2$ is plotted against x^* in Fig. 1, and the general behaviour of the potential for any higher value of l is the same, it is positive and goes to zero asymptotically as x^* approaches $\pm\infty$ and attains a maximum in between. From the Schrödinger form of the wave equation for Q and from the shape of the potential, it is evident that the scattering problem here is formally the same as that encountered in quantum mechanics for a one-dimensional potential barrier. A wave coming from spatial infinity is partially reflected by the effective potential, so that at large values of x we have both incoming and outgoing waves. On the other hand, as the Schwarzschild horizon acts as a sink for the radiation, there will be only waves entering the $r = 2m$ surface. Consequently the suitable asymptotic boundary conditions are $Q_\infty = A(k)e^{-ikx^*} + B(k)e^{ikx^*}$ and $Q_\infty = C(k)e^{-ikx^*}$ for x^* approaching $\pm\infty$ respectively. In analogy with the quantum mechanical problem we can define the reflexion and transmission coefficients $R = |B/A|^2$ and $T = |C/A|^2$. A fraction R of the incident wave escapes to spatial infinity and is accessible to a distant observer, whereas a fraction T of the radiation is absorbed by the black-hole and thereby lost in the process. An analytical integration of the equation for Q leading to the computation of R and T has been impossible in practice and recourse had to be taken to numerical integration. This has been carried out—as have further computations to be discussed later—for the lowest mode $l=2$ using a computer. Fig. 2 shows the plot of R against k^2 . In the limit of zero frequency the reflexion coefficient approaches the limit 1 independent of the scattering mass, and so in this limit no information about the latter is forthcoming. Nevertheless, the rate at which the reflexion amplitude B/A , and so R , decreases as a function of the frequency should be perceptible when a sufficient range of frequencies is included and, because this rate clearly depends on the scattering mass, the presence of the latter is “coded” into the outgoing radiation. This leads us at once to the

Fig. 2. The reflexion coefficient R as a function of k^2 , the square of the frequency, for odd-parity mode $l=2$.

physically more interesting phenomenon of the scattering of wave packets. By linear superposition we obtain an incoming wave packet at infinity with the spatial profile

$$\psi_{\text{in}}(x) = \int_{-\infty}^{+\infty} f(k)e^{-ikx} dk$$

and the corresponding outgoing or reflected packet

$$\psi_{\text{out}}(x) = \int_{-\infty}^{+\infty} (B/A) f(k)e^{ikx} dk$$

The latter travels out without spreading and is received by the distant observer. We choose the Gaussian function

$$f(k) = \frac{1}{2\sqrt{\pi}a} e^{-k^2/4a}$$

in order to obtain a simple model for an incoming wave packet, that is, $\psi_{\text{in}} = e^{-ax^2}$. As the parameter a , which measures the width of the wave packet, is varied, some interesting features emerge. For low values of a ($a \lesssim 0.01$), that is, for very broad incoming packets or equivalently for $f(k)$ sharply peaked at zero frequency, the reflected packet is practically unaffected. But, as the parameter a is gradually increased, ψ_{out} develops distinct maxima and minima that increase in number progressively, while their relative spacing undergoes a continuous change. As the parameter a , however, approaches approximately the value 1, that is, for a width of about the Schwarzschild radius, the process reaches a limit. Beyond this value of a , as the packet is made thinner, the outgoing packet will cease to develop new peaks and the relative spacing of these peaks will remain unaltered. In other words, any higher frequencies added to the original packet will have negligible effect on the scattered packet owing to their almost total absorption by the black-hole. As long as the incoming packet is spatially sharp enough, the reflected packet will manifestly carry information about the scattering mass. Fig. 3 shows an example of the “saturated” pattern corresponding to $a=1$. The spacing between consecutive peaks and, consequently, the lag in their arrival times are measures of the scattering mass, as the spacing in the actual radial distance is given by $\Delta r = 2m \Delta x$.

The total energy carried by a wave packet $\psi(x)$ at spatial infinity can be computed by adapting a method used by Edelman⁴. The result of this computation is that, for any mode l , the energy of the wave packet is given by

$$E = (c^5/32\pi G) (l-1)l(l+1) \int (\psi(x))^2 dx$$

where the integration is carried over the spatial extent of the wave packet. So the fraction of incident radiation scattered by the black-hole and reaching spatial infinity

Fig. 3. The outgoing wave packet $\psi_{out}(x)$ at spatial infinity corresponding to the incident Gaussian wave packet $\psi_{in}(x) = e^{-ax^2}$ with $a=1$.

Fig. 4. The fraction F of the incident energy carried by the scattered outgoing wave packet at spatial infinity plotted as a function of the parameter a .

is the ratio of the energies carried by the incoming and the outgoing wave packets and is readily computed as

$$F = \frac{\int (\psi_{out})^2 dx}{\int (\psi_{in})^2 dx} = \left(\frac{2a}{\pi}\right)^{1/2} \int (\psi_{out})^2 dx$$

In Fig. 4 the fraction F is plotted as a function of the width-parameter a . For an incident wave packet, the width of which is about a Schwarzschild radius ($a \approx 1$) approximately half the total energy is scattered and the rest absorbed by the black-hole.

We have confined ourselves so far to some results concerning the scattering of odd-parity gravitational waves of angular momentum $l=2$ by a Schwarzschild black-hole. The mathematical and numerical details omitted here, as well as the scattering of higher l modes, even-parity waves, scalar gravitational waves and finally electromagnetic waves, will be discussed elsewhere in a separate and more detailed paper.

I thank Professor C. W. Misner for many helpful discussions, Dr A. Lapidus and Mr Gary Russel for their help in carrying out numerical computations, and the authorities of the NASA Institute for Space Studies, New York, for allowing me to use their computer. Phase Change in the Upper Mantle above 350 km

BULLEN^{1,2} has used the Adams-Williamson relation in region B (upper 400 km in the mantle) to relate the rate of change of density in the Earth's interior to the rate of change of seismic velocity. The Adams-Williamson relation implicitly assumed that phase changes are absent. Recent interpretations of the velocity gradient in the mantle³ have re-emphasized the importance of phase changes in region C (between 400 and 900 km). Region B is often treated as a homogeneous layer, but I present here some evidence to show that phase change may also occur in this region.

A number of empirical equations which relate densities of common rocks and minerals with velocities of compressional waves⁴⁻⁶ show that velocity is linearly proportional to density

$$V_p = A + B\rho \quad (1)$$

where B has a value of about 3 (km/s)/(g/cm³). This relation has been applied to the calculation of density in various regions of the Earth from known seismic velocities⁷⁻⁹. For common rocks and minerals, bulk

sound velocity, C , which is defined as $(V_p^2 - \frac{4}{3}V_s^2)^{1/2}$, was also found to be linearly proportional to density. This relation may be expressed as

$$C = a + b\rho \quad (2)$$

where, for rocks and minerals with mean atomic weight about 21, b has a value of 2.36 (km/s)/(g/cm³) (ref. 10). This empirical relation was shown to follow closely the C versus ρ relation for a single material under large compression^{11,12}. Anderson¹³ gave a seismic equation of state relating the seismic parameter φ (which is identical to C^2) and ρ

$$\varphi/\varphi_0 = (\rho/\rho_0)^n \quad (3)$$

Fitting this equation to data for thirty-one selected rocks and minerals, the value for n is found to be about 3.

With increasing depth, both temperature and pressure rise. The implicit assumption in the application of any one of the empirical density velocity relations to the prediction of density in the upper mantle is that the effect of an increase of temperature and pressure with depth might change density and velocity in approximately the same ratio as that represented by the empirical relations. I have found¹⁴ that, in regions of high temperature gradient such as the upper mantle, this assumption is violated for the relation between V_p and ρ but is obeyed for equations 2 and 3. These relations are used to estimate the density differences at various depths in the upper mantle, corresponding to a given distribution of seismic velocities.

As noted by Anderson¹³, the seismic equation of state tends to predict smaller change of density than does Birch's equation of state at a given change of φ . In Fig. 1, ρ/ρ_0 is plotted against φ/φ_0 for the following equations: equation 6, with $b=2.36$ (km/s)/(g/cm³) and $C_0/\rho_0=1.8$ (km/s)/(g/cm³) as for most rocks and minerals (a is adjusted such that $C=C_0$ when $\rho=\rho_0$), equation 3 ($n=3$), and finally Birch's equation¹⁵

$$\varphi/\varphi_0 = \frac{1}{2}(\rho/\rho_0)^{\frac{2}{3}}[7(\rho/\rho_0)^{\frac{1}{3}} - 5] \quad (4)$$

Fig. 1 shows that in the range of interest for this study, the values for ρ/ρ_0 corresponding to equation 4 always fall between those corresponding to equations 2 and 3, with differences less than 3 per cent. Equation 2 always yields greater values for ρ/ρ_0 than does equation 3, with differences less than 5 per cent. The use of both equation 2 and equation 3, for the prediction of density in the upper mantle, probably would bring out an adequate range of uncertainty in the predicted densities due to the uncertainty in the density-velocity relations.

Table 1. VALUE OF C AND φ USED IN THIS STUDY

Depth (km)	Gutenberg		Johnson, V_p , and Ibrahim and Nuttli, V_s	
	C (km/s)	φ (km/s) ²	C (km/s)	φ (km/s)
150	6.03	36.4	5.94	35.3
350	6.82	46.5	6.90	47.6

The distribution of seismic velocities is critical for our study. Recent studies on body wave and surface wave data have given strong evidence for the existence of an extensive low velocity layer not far below the Mohorovicic discontinuity, thus lending support to Gutenberg's, rather than Jeffreys's, velocity distribution in the upper mantle. I chose two sets of C distributions (Table 1): one is from a combination of Gutenberg's¹⁶ V_p and V_s distribution; the other is from a combination of Johnson's¹⁷ CIT 204 for V_p and Ibrahim and Nuttli's¹⁸ V_s . The latter set is characteristic for the upper mantle beneath the western United States. The differences between these two sets of C distribution should give some indication of the uncertainty in the seismic models. Between 150 and 350 km, the differences in C , which correspond to these two sets of C distribution, are, respectively, 0.8 and 1.0 km/s; the ratios between the two values of φ at these two depths are, respectively, 0.78 and 0.74. Corresponding to equation 2 with $b = 2.36$ (km/s)/(g/cm³), the difference in density between 150 and 350 km is $\Delta\rho = 0.34$ and 0.41 g/cm³, respectively. Density at 150 km is about 3.3 to 3.5 g/cm³. Thus

$$\frac{\Delta\rho}{\rho_0} = 10 \text{ to } 12 \text{ per cent}$$

where the subscript 0 refers to the density at 150 km. According to the seismic equation of state (equation 3, $n = 3$), we obtain, respectively,

$$\frac{\Delta\rho}{\rho_0} = 8 \text{ to } 10 \text{ per cent}$$

Thus if the assumption of nearly uniform iron content in the upper mantle is correct, the increase of density between 150 and 350 is somewhere between 8 and 12 per cent.

If there are significant changes of mean atomic weight with depth in the upper mantle, the calculation breaks down. Greater density for a given velocity usually corresponds to greater mean atomic weight, and vice versa. Thus if there is an increase of mean atomic weight with depth in the upper mantle, the actual density change would be greater than those calculated above. On the other hand, if there is a decrease of mean atomic weight with depth, then the actual density change would be smaller than those predicted by the empirical equations. Present evidence for significant change of mean atomic weight with depth in the upper mantle is, however, almost totally absent. Although evidence on the uniformity of mean atomic weight in the upper mantle is equally meagre, the assumption of uniform mean atomic weight is the least complicated. Furthermore, Earth models with an increase of density of this magnitude between 150 and 350 km have been found which satisfy all relevant geophysical data including the periods of free oscillations, the phase and group velocities of surface-

Fig. 1. ρ/ρ_0 plotted against v/v_0 for equations 2, 3 and 4.

waves, and the total mass and moment of inertia of the Earth¹⁴.

The composition of the upper 400 km of the mantle is usually considered to resemble that of some varieties of peridotite in which olivine is the predominant constituent. Thus the effect of gravitational self-compression between 150 and 350 km may be estimated, to a good approximation, from that for a homogeneous layer of olivine. The isothermal bulk modulus for olivine at 1 atmosphere and room temperature is 1,270 kb (ref. 19). Temperature at the depth of 150 km is about 1,500° C (ref. 20). Using $(\delta K_T/\delta T)_P = -0.208$ kb/deg (ref. 19), the value of K_T at this temperature becomes 950 kb. The corresponding value at a higher pressure may be estimated. The experimental value of $\delta K_T/\delta P$ for olivine is 5.1 at room temperature¹⁹. The change of this parameter with temperature, however, is unknown. I used the values $(\delta K_T/\delta P)_T = 4$ at $T \approx 1,500^\circ \text{C}$. Thus the value of K_T for olivine at 150 km, where the pressure is about 50 kb, is 1,150 kb. This value of K_T may be used to estimate the change of density from 150 to 350 km from isothermal compression alone; the result will be corrected later for the effect due to the difference in temperature between these depths. Birch's equation of state¹⁵ is used to calculate the change of density caused by isothermal compression

$$\frac{2}{3} \frac{\Delta P}{K_T} = \left(\frac{\rho}{\rho_0} \right)^{\frac{2}{3}} - \left(\frac{\rho}{\rho_0} \right)^{\frac{1}{3}}$$

The pressure difference between 150 and 350 km is about 70 kb (refs. 10, 21, 22). The corresponding value for ρ/ρ_0 is 1.056, where the subscript 0 refers to the density at 150 km. Thus the maximum change of density due to self-compression in this depth range is 5.6 per cent. Assuming a temperature difference of 300 degrees¹⁵ and using a coefficient of 2×10^{-5} per degree for thermal expansion, it follows that $\Delta\rho/\rho_0 = 5$ per cent, where $\Delta\rho$ is the change of density from 150 to 350 km from self-compression.

Thus about one third to two thirds of the total increase of density between 150 and 350 km (8 to 12 per cent) cannot be accounted for by the self-gravitational compression and may be associated with phase transitions in mineral assemblages occurring in this range of depth. Considerable discussion has been given to the breakdown of aluminous pyroxene to pyrope-garnet plus low-alumina pyroxene^{23, 24}. Whether this suggestion is sufficient to account for the density change due to phase

transition as indicated in this study is not discussed here.

I thank Professors Keisuke Ito and John Verhoogen for helpful discussions. This work was supported by a US National Science Foundation grant.

Thermoluminescence Dating applied to Volcanic Lava

THE thermoluminescence dating technique applied to volcanic lava has been reported by Aitken *et al.*¹ In their preliminary experiments, grain sizes of between 40 and 80 μ m in diameter were selected by Franz-type magnetic separators, and a spurious glow was observed even from some young lavas. This spurious glow was attributed to the impurities which are difficult to separate from the luminescent grains with magnetic separators.

Fig. 1. A, Artificial TL glow (250 rads beta, ⁹⁰Sr); B, natural TL glow of feldspar from the Pompeii ash.

Fig. 2. Susceptibility of the feldspar to radiation dose (⁹⁰Sr source).

Our new approach to this technique of volcanic rock dating is to select crystalline grains from a rock for measurement of the thermoluminescence. Three kinds of crystals are commonly found in lava; they are light green, dark green or white in colour. The volcanic ash we examined first is the one believed to have destroyed Pompeii. The needle shaped, transparent feldspar from this ash was identified as orthoclase by X-ray diffraction and optical methods. The other coloured crystals were found to be insensitive to the thermoluminescence effect.

Ten to twenty crystals of 0.5 to 1 mm in diameter were selected for thermoluminescence measurement. The crystals were ground with 600 grade carborundum and water so that they had a flat bottom in order to make good contact with the tantalum heating strip. This arrangement also provided a repeatable geometry for the thermoluminescence measurement. The induced thermoluminescence by the natural radioactive isotopes or by artificial irradiation was measured conventionally by a photomultiplier tube and the heating rate used was 20° C/s in an atmosphere of nitrogen. The natural glow and artificial glow of a sample are shown in Fig. 1. The scale of the glow intensity for curve A should be multiplied by 10 when it is read. The 220° C peak induced by artificial irradiation was not found in the glow curve because it was drained by the geological temperature during burial. For dating purposes, the total glow in the temperature region between 320° C and 420° C was chosen, using the "ordinate ratio test" technique². The ratio of the natural glow to the artificial glow at the same temperature was plotted against the heating temperature and a plateau appeared above 320° C. In this way, the thermal bleaching during burial is assumed not to affect the trapped carriers. No allowance, however, has been given for the possibility of the decay of trapped carriers by the tunnelling effect, which is believed to be negligible. The susceptibility of the sample to radiation was calibrated using a ⁹⁰Sr beta source and is shown in Fig. 2. The age determination of the sample is based on the assumption that the beta and gamma particles have the same effectiveness in inducing thermoluminescence. Also, because grains are chosen so that their diameters are much bigger than the range of the alpha particles from the natural content of uranium and thorium, the annual dose contributed by the alpha particles is considered to be insignificant³. The age of this sample was found to be of the right order using these assumptions. The most significant result is that the other lavas, which were

Table 1

Sample	Annual dose (rad/year) (U + Th + K + cosmic ray)	Archaeological age (year)	TL age (year)
Ash	1.1596	1821	1797 ± 160
Grey lava	2.444	64 ?	0
Brown lava	1.886	64 ?	0

collected on the surface of the upper slope of Vesuvius, and are believed to be young (the latest major eruption was in 1906), did not show any spurious glow, although the magnetically separated portion of these samples did give a spurious glow.

I thank Dr G. L. Hendry of the Department of Geology of the University of Birmingham for the X-ray diffraction and the potassium content analysis, Dr J. I. Langford of the Department of Physics for optical identification of the mineral and Miss J. Thompson of the University of Oxford for the uranium and thorium content measurements. A full programme is under way for examining more samples, and I would like to appeal for the donation of volcanic ashes of known ages in order to establish the technique.

Long-lived γ -Ray Emitting Nuclide Silver-108m found in Pacific Marine Organisms and used for Dating

DRIED tissues of several marine organisms collected in 1964 from widely separated regions of the North Pacific have turned out to contain ^{108m}Ag , a γ -ray emitting man-made nuclide with a half-life reported¹ to be greater than 100 yr. This seems to be the first observation of ^{108m}Ag in any organism as the apparent consequence of global fallout. This nuclide promises to be useful for large scale labelling and dating. We have used it to follow the progress of a specific oceanic water mass.

The short-lived (253 days) ^{110m}Ag was determined in 1964 (ref. 2); on the other hand, a recently installed two-dimensional γ -ray spectrometer of a type developed by the Hanford group³ was used for measuring ^{108m}Ag . Table 1 lists the activities of ^{108m}Ag found in samples of squid, mussel, lobster, and tuna fish collected in 1964–65 at widely separated oceanic and coastal locations. The concentrations of ^{110m}Ag measured in 1965–66 are also listed, together with the individual activity ratios. All activities were extrapolated arbitrarily to conditions on August 7, 1964, when the first oceanic squid sample² to reveal ^{110m}Ag was collected. The last column of Table 1 contains the dates of apparent nuclear origin implied by the activity ratios according to the assumptions indicated. Table 2 describes the specimens with regard to place of collection, species and sample size in terms of the wet weight of the organs counted.

Table 1 lists the usual estimated (one sigma) standard counting errors. The uncertainties in the date values in the last column were computed from the errors of the ^{108m}Ag and ^{110m}Ag activities. Uncertainties in half-life should affect the earliest date by no more than 15 days and other dates by even less. An initial $^{110m}\text{Ag}/^{108m}\text{Ag}$ activity ratio of 162 was assumed in the dating computations, this being the value reported immediately after activation of natural silver in a reactor experiment⁴. It is difficult to speculate on the similarities and dissimilarities between the conditions existing in a reactor and during the explosion of a nuclear weapon, but, taking into account the natural abundances of ^{107}Ag and ^{109}Ag and the decay rates of ^{110m}Ag and ^{108m}Ag , an initial activity ratio of 162 implies very nearly equal activation cross-sections for the production of ^{110m}Ag and ^{108m}Ag . In view of this and the reported⁵ similarity between the nuclear structures of the two sets of silver states, it seems reasonable to use 162 in the case of nuclear weapons.

^{108m}Ag was calibrated by standardization of the two dimensional spectrometer with a source of pure ^{108m}Ag generously supplied by the Los Alamos Scientific Laboratory. This source was first calibrated at Scripps by comparison with a standardized point source of ^{137}Cs (using the ^{108m}Ag decay scheme shown by Lederer, Hollander and Perlman⁶, with an EC/IT branching ratio of 91.5/8.5 (ref. 4)). In 1964, ^{110m}Ag had been calibrated by reference to the same source of ^{137}Cs . Our experience⁶ suggests that the absolute accuracy of calibrations of standards of this sort usually are not better than ± 5 per cent.

The salient feature of ^{108m}Ag is that it is an artificial γ -ray emitter with an exceptionally long life, longer than any other man-made γ -ray emitter reported anywhere in the biosphere. The slow decay of ^{108m}Ag suggests that it would be useful, with ^{110m}Ag , for very large scale labelling and experiments. Both these nuclides seem to be activated together when ordinary silver is exposed in reactors and in the detonation of certain weapons.

An idea of the use of $^{110m}\text{Ag}/^{108m}\text{Ag}$ dating can be gained by considering how the animals listed in Table 1 could have come into contact with the observed silver nuclides. This will require reference, first, to reported dates when specific large weapons were tested; second, to the reported character of the global fallouts that followed; third, to the motion and stratification of upper layers in the Pacific;

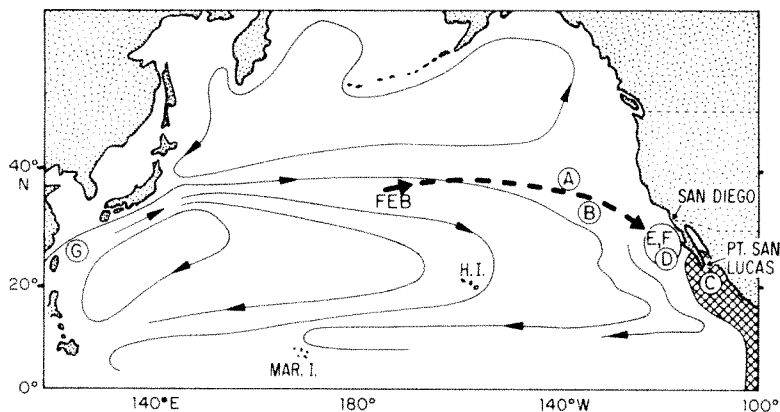

Fig. 1. Locations where organisms contained long lived silver radionuclide were collected. Arrows show generalized major oceanic circulations; circles show collection locations; cross-hatching shows yellowfin tuna fishery regions; - - - , suspected spring migration of albacore caught off California (regions E, F) June-July albacore fishery.

and fourth, to the probable environment and characteristic behaviours of the several organisms.

The testing of very large nuclear weapons was renewed abruptly on October 23, 1961; other tests were made in 1962, especially in the autumn. The observed silver nuclide ratios in Table 1 indicate the absence of large amounts originating in 1958 and earlier. Thus the observed silver nuclides most likely originated within the 1961 and 1962 testing periods.

After the 1961-62 weapons tests, there were intense global fallouts during the spring of 1962, 1963 and 1964, especially intense at latitude 40°-50° N (ref. 7). Presumably the observed ^{108}mAg and ^{110}mAg could have entered the sea any time after October 23, 1961, but the largest fraction of silver of 1961 origin should have entered in the spring of 1962. Lesser amounts that had been stored in the stratospheric reservoir should then have followed late in 1962, and also in 1963 and 1964. But, after the summer of 1962, and especially after October 1963, all the 1961 fallout must have been mixed with some that originated in 1962. This mixture would be expected to have entered the ocean most rapidly in the spring of 1963, yet some with slightly different silver nuclide mixtures should have fallen later, especially in the spring of 1964.

Finding mixtures of silver nuclide ratios in organisms corresponding closely to late origin therefore indicates that either very little radioactive silver was formed in 1961 compared with 1962, or the species with the late origins lived in regions where silver was dispersed or depleted rapidly, and they adjusted rapidly to changes in silver in their environment. The first alternative is unlikely because of findings in the case of the albacore, as will be shown later.

Table 1 shows that all but one of the species inspected had large fractions of 1962 fallout as indicated by the radio-silver ratios. One squid (A) contained a nuclide ratio that might have come from the autumn of 1962 when the final large tests of this post-moratorium series took place. This squid was feeding at the surface when captured. It seems therefore that its feeding region was being rapidly depleted of silver (and perhaps of other trace metals), and also that the biological half-life of the species was short—of the order of a few weeks or months.

Table 1 shows that another squid (B), some tropical tuna (C) and some lobsters (D) from a small island also contain silver nuclide ratios that suggest associations with water masses which were constantly depleted of silver, again suggesting rapid turnover of silver traces in the organisms or in their food. The lobsters of Guadalupe (D) usually live in shallow layers, and presumably, from the silver nuclide ratio found, they depend on food with similar environment. Yellowfin tuna are caught at the surface; the silver ratios they contain suggest that

their food comes from regions where there is a rapid turnover of silver. Another interesting factor in the environment of this population will be discussed later.

Byssal mussels (G) were collected from tide pools in a calcareous apron of Okinawa where rain containing relatively high concentrations of fallout struck the organisms directly during periods of low tide, and might also have accumulated and been retained in their fixed substrate and in other sessile organisms living nearby. In addition to recent fallout, therefore, early fallout rich in 1961 silver nuclides could well have remained available to the mussels until 1964 when they were collected. Their nuclide ratio of intermediate value suggests this possibility.

The two albacore individuals (E and F) had a remarkably different silver nuclide ratio that can best be understood with reference to surface and subsurface surveys of ^{137}Cs in the Pacific^{8,9}. It can be shown that the ratio $^{110}\text{mAg}/^{108}\text{mAg} = 9$ corresponds within error to activation on October 23, 1961, when the first large nuclear test after the moratorium took place. This strongly suggests that these albacore individuals had recently been in contact, directly or through their food, with "almost pure" 1961 fallout silver radionuclides. Because completely unmixed 1961 fallout could not have entered the ocean later than the summer of 1962 (and presumably the largest fraction entered still earlier during the intense 1962 spring fallout peak), these albacore had evidently encountered and been exposed to a body of water or food that had been quite isolated for at least 2 yr from sources of recent fallout.

In Fig. 1 a suspected¹⁰ route of annual migration of the albacore population of the North Pacific is sketched (as a dashed line) leading into the June-July fishing ground (E, F) where the two individuals of Table 1 were caught. Albacore fishing usually begins in this general area, and then moves northward along the coast during the summer. Finally, the albacore apparently return to the central North Pacific later in the autumn. The habits of the fish immediately before appearing off Southern California and Baja California are not well known. But the fish are caught on the surface thereafter.

A mechanism now can be suggested to explain how a trace element might be isolated and kept pure quite effectively for several years in thin subsurface layers while moving thousands of miles, and thus how the albacore could have encountered essentially pure 1961 radioactive silver. The North Pacific circulation brings northern surface waters, and also the shallow subsurface layers supporting most of the marine organisms, eastward and southward past California. Fig. 1 shows the generalized circulation^{11,12} and also the collecting locations of the present experiment. It has become evident from surveys^{8,9} of fallout ^{137}Cs that fallout distributions in the North Pacific depend, after a few years, on oceanic circulation as well as on the distribution of initial fallout inputs. Relatively high inputs of fallout entering the sea near 40° N apparently are transported eastward and southward to latitudes of 10°-20° N, and much is then carried westward in low latitudes. Surface and shallow subsurface ^{137}Cs distributions measured in 1964-68 suggest transport rates for this movement of 2-3 cm/s, consistent with hydrographic predictions^{11,12}.

Detailed sampling of ^{137}Cs at numerous depths above 300 m has revealed thin stratifications delineated by high concentrations of ^{137}Cs most commonly between about 70 and 150 m. In overlying waters ^{137}Cs frequently was much less concentrated. These high subsurface concentrations of ^{137}Cs frequently were associated with salinity minima which have long been attributed to high rainfall in northern

latitudes. By 1968, the most intense subsurface ^{137}Cs stratifications were found between 20° and 10° N, and as far west as the longitude of Hawaii. When this 1968 picture of isolated and moving lenses or strata of fallout lying at shallow depths (as suggested by hundreds of measurements of ^{137}Cs in the Pacific) is extrapolated back to the summer of 1964, it is apparent that the moving front of the water contaminated by early post-moratorium fallout near 40° N must have reached the latitudes of the June–July albacore fishery (E, F) south of San Diego about when the albacore of Table 1 were caught. That is, the oldest fallout of 1961 and spring 1962 origin would have entered the region, much of it isolated below the mixing forces in the surface layers. These albacore must have had a unique opportunity for contacting almost unmixed 1961 fallout in 1964.

The situation of the yellowfin tuna is somewhat different. This is a tropical fish ranging to the equator and scarcely reaching temperate latitudes (Fig. 1). Individuals reaching Point San Lucas by summer 1964 were just too early to meet the old fallout front borne by currents coming down from the north. The yellowfin tuna must have been exposed, however, to aerial fallout containing young 1962 silver activities.

No evidence of hazard to humans should be inferred from our finding of long-lived $^{108\text{m}}\text{Ag}$ in commercially collected tuna. The activities we measured were so small as to be difficult even to detect—very much smaller than activities that are natural to the tissues.

We thank Professor C. L. Hubbs for collecting lobster tissues, and Professor C. L. Osterberg for a squid specimen. Many people helped to collect the other samples. We also thank Drs M. E. Bunker, J. W. Starner and S. G. Schmelling for sources of $^{108\text{m}}\text{Ag}$. Dr G. Harbottle sent his unpublished report¹ concerning decay of $^{108\text{m}}\text{Ag}$ and also several other valuable references. This work was supported by the US Atomic Energy Commission and the US Office of Naval Research.

Stable Isotope Study of the Palaeoenvironment of the Neolithic Site of Nea Nikomedeia, Greece

THE Neolithic mound of Nea Nikomedeia¹ lies some 25 km north-west of the mouth of the river Aliakmon, in the Macedonian Plain of Greece. Field evidence suggests that at the time of the Neolithic occupation the low land near the site, drained in the last century, may have been

occupied either by a lake or by an arm of the Gulf of Thermai².

Although shellfish remains are not abundant in the deposits, shells of the common cockle, *Cerastoderma edule* (Linne), are sufficiently abundant in some areas to indicate that they were eaten. Because the site is distant enough from the present coastline to have dissuaded prehistoric man from carrying back shellfish before eating them, it seemed likely that any information relating to the habitat of these cockles might shed light on the nature of the water body nearer the site. To this end, oxygen and carbon isotopic analyses of samples of a few of the shells have been carried out.

Fig. 1. Oxygen and carbon isotopic composition of the edges of cockle shells (*Cerastoderma edule*) from Nea Nikomedeia, expressed as a deviation in parts per thousand from the PDB standard.

The basis of this approach is a systematic survey by Keith *et al.*³, who showed that a knowledge of the carbon and oxygen isotopic composition is sufficient broadly to characterize the aquatic environment of a mollusc. In Fig. 1, the oxygen and carbon isotopic composition of samples taken from the edges of a number of shells from the site of Nea Nikomedeia are shown. It will be seen that the range of oxygen isotopic composition ($\delta^{18}\text{O}$) is from -1 to -5 parts per thousand, and that the range of carbon isotopic composition ($\delta^{13}\text{C}$) is from -3 to -7 parts per thousand, both relative to the PDB standard⁴. These values suggest an estuarine environment. (Precise calibration in terms of the PDB standard is difficult because none of the original material is now available. The definition of the standard is also generally regarded as implying a particular extraction procedure including reaction at 25°C , and differing in several respects from that adopted here. For the purposes of this work, the precise meaning of the zero point in Figs. 1 and 2 is unimportant.)

More detailed work on shells from an estuarine environment was carried out by Mook and Vogel⁵, who analysed shells collected at varying distances from the sea along two estuaries adjoining the North Sea. Their work confirmed that these molluscs deposited both carbon and oxygen in the carbonate of their shells in isotopic equilibrium with the bicarbonate ion in the water in which they grew. The oxygen isotopic composition of the water and hence of the bicarbonate varies with distance from the sea, as the relative proportion of sea water, $\delta^{18}\text{O} \approx 0$, and fresh water, $\delta^{18}\text{O} \approx -10$ parts per thousand, varies. At the same time the carbon isotopic composition changes, for the bicarbonate in sea water has $\delta^{13}\text{C} \approx +2$ parts per thousand, while in river water the bicarbonate has $\delta^{13}\text{C} \approx -12$ parts per thousand as a result of the incorporation of isotopically light carbon derived from the decomposition of plant matter.

Fig. 2. Oxygen and carbon isotopic composition of sequential growth increments from shell No. 5 of Fig. 1. Samples are lettered from the edge (a) inwards to (n).

Mook and Vogel found that in each river, analyses plotted as our Fig. 1 fell near a straight line, the points indicating various mixtures of the sea water and river water end members. At first it seemed that our results (Fig. 1) displayed the same feature; that is to say, prehistoric man collected cockles at various points along a former estuary.

To investigate the matter further, successive growth increments were analysed in some of the shells. The result of this procedure for one shell (No. 5 in Fig. 1) is shown in Fig. 2. The points are lettered from the edge of the shell inwards. The procedure was as follows. The shell, length about 35 mm, was cut in half along a rib, and one edge was polished to reveal the growth laminae. The inner part of the shell, where growth layering parallel to the shell is visible, was filed away and discarded, after which samples weighing about 0.3 mg were taken with a triangular file at intervals of about 1 mm along the rib. This ensured that each sample represented a well defined growth interval. The samples were roasted at 450° C *in vacuo* for 30 min to remove organic matter, after which carbon dioxide was released by the action of 100 per cent orthophosphoric acid at 50° C (refs. 6 and 7). The gas was compared with a running standard using a double-collection mass spectrometer, and the results were calibrated by analysing standard carbonates under the same conditions. The overall reproducibility of the analyses during this series was about ± 0.15 parts per thousand.

It is clear from Fig. 2 that the shell lived in an extremely variable environment. Sample *n* implies more or less undiluted Mediterranean water, while sample *b* probably represents a mixture of about one part sea water to two parts river water. The variation is cyclic; our analyses extend through two complete years. This is confirmed by a visual examination of the shell, which shows an alternation of clean and dirty colour. The isotopic variation seems to be consistent with the Mediterranean climate, in which rainfall and therefore river flow are intensely seasonal. In the mountains of northern Greece, where the river Aliakmon rises, monthly rainfall in the dry months of July to September is only about 1½ inches, while in some winter months it may be ten times as much. Evidently this particular shell died, and presumably was eaten, in the spring. Sample *b*, not far from the edge, represents the lowest salinity of the previous winter. Samples *f* and *g* represent the previous summer, and so on (note that no special care was taken to space the samples equally, so that the distribution of points does not accurately represent the distribution of growth through the year).

In the light of Fig. 2, it now seems that Fig. 1 should be interpreted as representing variation in the season of

collection among the shells sampled, rather than (or as well as) variation of position of collection along an estuary. There seem to be at least three separate areas of knowledge into which this study extends.

First, the palaeoenvironment of the Neolithic occupation site is better understood. The water body near the site was evidently freely connected with the sea as an estuary. In summer, the water would have had the salinity of the open sea, while in winter the salinity was much reduced by river inflow. It may be interesting to examine the fish bone in the food refuse in the light of this knowledge. The water would have been inhabitable to certain species only in the summer, so that the presence or absence of such species may indicate whether the settlement was deserted in summer as cattle were taken to higher ground, or whether it was continually occupied.

Second, it seems that even in an estuarine environment, where the effect of temperature on the isotopic fractionation between water and carbonate is swamped by the much greater changes in the isotopic composition of the water itself, we are able to determine the season of the year in which a shell was collected. Clearly a greater number of samples, critically selected, must be analysed before a reliable assessment can be made of the proportion of the year during which the site was inhabited, and at this particular site we are limited by the fact that shellfish was not an important part of the diet in any case. Even so, the definite information provided will be of value.

Third, this may prove a valuable tool in the wider investigation of climatic change. At least in the Mediterranean region, where estuarine mixing is not complicated by tidal effects, it may prove possible to utilize seasonal changes in the isotopic composition of fossil estuarine mollusc shells to discover the extent to which the seasonal rainfall pattern of the region has altered during the Pleistocene. This could greatly improve our understanding of the Mediterranean pluvial phases which seem to have coincided with the glaciations in more northerly latitudes.

I thank Dr R. J. Rodden, director of the excavations at Nea Nikomedeia, for putting samples at my disposal for this study. I also thank Mr M. A. Hall, who performed most of the analyses presented.

Dipole Effect on the Vapour Pressure of Aliphatic Polar Liquids

KIRKWOOD's theory¹ for the interaction of a dipole-containing dielectric sphere with a dielectric continuum is used here in estimating dipole and dielectric effects on vapour pressure *p*. There have been many general and approximate examinations of such effects, including, for instance, the relationship of permittivity with "internal pressure"², the effect of a dipole on the boiling point³ and, for mixtures, the effect of polarity on the excess functions⁴, but there have been none involving a direct comparison of prediction with observation.

We approximate the nonpolar dispersion interactions by equating these to the values for "isostructural" hydrocarbons obtained by summarily replacing⁵ N or O by CH₃. For example, for both acetone

Fig. 1. Log p (observed are full lines, and calculated are filled circles) and log p_{ref} (isobutane, broken line) against inverse temperature. Acetone, upper line, -70 to 50°C . Nitromethane, lower line, 0 to 40°C .

and nitromethane we take isobutane as the nonpolar reference liquid. Seemingly anomalous polar liquids like ether (slightly more volatile than its reference liquid, pentane, contrary to what is expected for an apparently additional polar interaction) fall within our scope, which we have limited to liquids clearly suitable to being treated as continua. Such are the Onsager liquids, those for which the Onsager equation⁵ yields dipole moments from the liquid permittivities in good agreement (± 10 per cent) with the gas-phase values.

The appropriate Legendre function¹ yields for the work w_e of creating a dipole moment μ in a dielectric sphere,

volume v , of internal permittivity ϵ_i , surrounded by a dielectric continuum of permittivity ϵ ,

$$w_e = w_0 + \frac{4\pi\mu^2}{3v} \cdot \frac{\epsilon_i - \epsilon}{\epsilon_i(2\epsilon + \epsilon_i)} \quad (1)$$

(w_0 is the dielectric-independent self-energy term¹¹ which will be eliminated). For transfer of the sphere from vacuum to a dielectric of permittivity ϵ the work of immersion w is obtained by subtracting from (1) the corresponding expression with $\epsilon = 1$, giving

$$w = -\frac{4\pi\mu^2}{3v} \frac{\epsilon - 1}{(\epsilon_i + 2)(\epsilon_i + 2\epsilon)} \quad (2)$$

Assuming that the difference in chemical potential between a polar and corresponding nonpolar reference liquid arises only from electrostatic interactions which we equate with w , and neglecting non-ideality of vapours, we obtain for the respective vapour pressures p and p_{ref}

$$p = p_{ref} \cdot \exp(w/kT) \quad (3)$$

In (2) we take for v the molecular volume in the liquid, $M/\rho L$, and put $\epsilon_i = n^2$, n being the Na-D refractive index.

We test the equations for the well-documented cases⁶⁻¹⁰ of acetone and isobutane, and nitromethane and isobutane, for which data are available over extensive temperature ranges. Fig. 1 illustrates the satisfactory agreement between the values calculated from (3) (filled circles) and the observed p values (lines).

On the other hand, for ethers and tertiary amines (μ appreciable but ϵ small) equation (2) yields numerical values of $w/kT \ln(10)$ smaller than 0.1 . Such values are indistinguishable from zero in view of the approximations in our model, and log p for such polar liquids, when plotted against log p_{ref} , should thus yield a line of unit slope through the origin. This prediction from the Kirkwood equation is again quite satisfactorily substantiated (Fig. 2). The perceptible scatter here serves to illustrate the extent

Fig. 2. Logarithmic plot of vapour pressure p of polar liquid against p_{ref} of reference liquid, for polar liquids having $w \sim 0$. Temperatures in the range -12 to 27°C , except for tripropylamine, at 157°C . From left to right, polar liquids having log $(p/\text{mm Hg})$ between:

1 and 2: 1,2-diethoxyethane, dioxane, triethylamine, dipropyl ether, di-isopropyl ether.

2 and 4: ethylpropyl ether, methylpropyl ether, diethyl ether, trimethylamine, tripropylamine, methyl ethyl ether, dimethyl ether.

[Broken lines are ± 0.25 units from full 45-degree line through (0,0).]

Fig. 3. Logarithmic plot of vapour pressure p of polar liquid against p_{ref} of reference liquid (open circles): also of p against calculated values (filled circles)⁸⁻⁹. Temperatures in range 10° – 30°C . From left to right, polar liquids having log $(p/\text{mm Hg})$ between:

-0.5 and 0 : 2-octanone, 2-heptanone.

0 and 1 : dimethylformamide, cyclohexanone, mesityl oxide.

1 and 2: 1-nitropropane, ethylpropionate, 2-nitropropane, n-propylacetate, nitroethane, nitromethane, methylpropionate, n-propylformate, 2-butanone, ethylacetate.

2 and 3: tetrahydrofuran, methylacetate, acetone, methylformate, acetaldehyde.

[Where necessary, tags identify associated filled and open circles. 45-degree line through (0,0), ± 0.25 , again shown.]

of approximation in our assumption for the nonpolar interactions.

Fig. 3 involves liquids for which $w/kT \ln 10$ is appreciable. For these, the dielectric and vapour pressure data are limited effectively to one temperature⁷⁻¹⁰ (dipole moments being often values in the solution-phase⁶), so a plot of the type of Fig. 2, rather than of Fig. 1, is presented. The reference-hydrocarbon vapour pressures p_{ref} , plotted logarithmically against polar-liquid values p , can be seen to have a wide scatter (open circles). But when $\log(p_{\text{ref}}) + w/kT \ln(10)$, representing calculated polar-liquid values, are plotted against $\log p$ (filled circles), the graph becomes again a distribution of points about the (0,0) line of unit slope, once more supporting equation (3).

Errors clearly arise from three main sources—the nonpolar-interaction assumption discussed with Fig. 2, experimental error in the data, and intrinsic inadequacies of the model. The second can be appreciable. McLellan⁶ noted that gas-phase μ values for a particular substance can be uncertain by as much as 0.2 D or more. Only part of the deviation occurring in Fig. 3 then arises from the model, as discussed in detail by Onsager⁵ and Kirkwood¹. The chief merit of the model as deployed here is its freedom from adjustable parameters.

Aromatic compounds fail to conform to the model, presumably because of breakdown from conjugation effects in the assumption of a nonpolar interaction. In this connexion compounds containing second-period and larger atoms have been omitted because measurements on the appropriate reference liquids are lacking. These exclusions apart, all Onsager liquids examined did conform.

High Strength, High Modulus Graphite Fibres from Pitch

FIBRE composite technology has advanced rapidly in recent years with the development of several types of strong, stiff fibres, for example, S-glass, boron and graphite. The superior structural efficiency of graphite fibres is due to a combination of high strength and modulus and low specific gravity. The high modulus, and to some extent the high strength, is thought to be a consequence of the high degree of orientation and the small size of the graphite crystallites^{1,2}. To date such graphite fibres have only been obtained from synthetic, oriented, polymeric precursor fibres, of which the two main examples are rayon and polyacrylonitrile (PAN). In this laboratory high performance, highly oriented continuous graphite fibres have been produced from a number of readily available and inexpensive pitch precursors.

The crude pitch, for example, asphalt, is first refined by distillation and pitch fibres melt-spun onto spools. The fibres are then subjected to controlled oxidation and car-

Fig. 1. Debye-Scherrer X-ray diffraction patterns of (a) carbonized (1,000° C) pitch fibres, (b) graphitized (2,500° C) fibres and (c) "stretch-graphitized" (2,500° C) fibres of average Young's modulus $\sim 38 \times 10^6$ pounds/inch².

bonization (to 1,000° C) similarly to methods previously used³. The resulting carbon fibres (representing a weight yield in excess of 65 per cent based on the refined pitch) are of uniform diameter (5–50 μm) and exhibit tensile strengths to 1.75 GN/m² (250,000 pounds/inch²) and Young's modulus in the range 20–50 GN/m² ($3\text{--}7 \times 10^6$ pounds/inch²). Their specific gravity is ~ 1.6 . Debye-Scherrer X-ray diffraction patterns of a fibre bundle (rotated axially) indicate that the carbon is isotropic and substantially amorphous (Fig. 1a). From the X-ray line broadening the crystallite dimensions are $L_c \sim 1 \text{ nm}$ (10 Å) and $L_a \sim 1.7 \text{ nm}$ (17 Å).

The production of highly oriented graphite from these carbon fibres requires carefully controlled elongation of the fibre during graphitization in the temperature range 2,000° to 2,800° C; to date uniform elongations as high as 140 per cent have been obtained on continuous fibres. The effect of the high temperature axial plastic deformation is preferentially to orient the crystallites, tending to align the graphite basal planes parallel to the fibre axis. Analogous effects have been observed in graphite fibres prepared from both rayon⁴ and PAN⁵, while a similar deformation-induced anisotropy in bulk glassy carbon has recently been reported⁶.

Figs. 1a, b and c show Debye-Scherrer X-ray diffraction patterns for carbon fibre, carbon fibre graphitized without elongation and "stretch-graphitized" fibre, respectively. The high degree of preferred orientation obtained by

Fig. 2. Relation of the axial Young's modulus to the basal plane orientation in graphite fibres.

"stretch-graphitizing" these pitch carbon fibres is evident from the (002) arc length in Fig. 1c.

Fig. 2 shows the relationship between the axial Young's modulus of a number of graphite fibres, produced by "hot-stretching" to different elongations at $\sim 2,500^\circ\text{C}$, and the fibre preferred orientation. The orientation is represented by the angular half width, Z° , at half peak density round the X-ray (002) diffraction arc profile. A low value of Z° represents a pronounced degree of orientation. The modulus was measured by standard tensile test (Instron, 1 inch gauge length) and is uncorrected for porosity. Fibre diameters were measured using a shearing image eyepiece. For comparison the corresponding data available for graphite fibres produced from rayon and PAN, together with the theoretical lower bound curve for the homogeneous stress model², are included. To date, oriented graphite fibres have been produced from pitch precursors which exhibit strengths to 2.6 GN/m^2 ($375,000\text{ pounds/inch}^2$) and Young's modulus greater than 440 GN/m^2 ($70 \times 10^6\text{ pounds/inch}^2$). Bulk densities are similar to those of other graphite fibres.

Fig. 3. Bright field transmission electron micrograph of a thin longitudinal section of a "stretch graphitized", high modulus fibre ($\times c. 106,670$). Inset is the electron diffraction pattern from this area.

Transmission electron microscopy of a thin fibre section, cut on a microtome (Fig. 3), shows narrow elongated structural units lying parallel to the fibre axis. The electron diffraction pattern gives further evidence for the preferred orientation. This fibrous structure appears to be similar to that previously observed in rayon⁷ and PAN^{1,8} graphite fibres. For the latter structure an end-to-end stacked, turbostratic crystallite model, in which the individual crystallites are separated by grain boundaries and narrow voids, has been proposed^{8,9}. It is interesting to note that a similar microstructure is obtained in the present graphite fibres, derived from an essentially amorphous pitch, as is obtained in fibres produced from oriented polymeric precursors. Oriented, high modulus graphite fibres have also been produced recently from glassy carbon fibres made from thermosetting resins.

A more complete structure and property characterization of these fibres will be published at a later date.

BIOLOGICAL SCIENCES

Quantitative Study of Cells reacting to Skin Allografts

THE cellular response to a strongly antigenic skin allograft is biphasic. Before rejection of the graft, cellular proliferation in the regional lymph nodes is largely confined to the intermediate (paracortical) zone. Then, at the time of onset of rejection, mitotic activity develops in the outer cortical zone and germinal centres are formed; simultaneously, or a little later, plasmacytes appear in the medulla of the nodes¹. The second phase is temporally, and probably also functionally, correlated with the production of humoral antibodies directed against antigens of the skin graft donor. The function of the first phase (during which antibodies are not normally detectable in the serum) is less clear, but is probably concerned with the development of the cellular mechanism for rejecting the graft. In broad terms, this cellular mechanism may be thought to consist of the production of "sensitized" lymphocytes, which become localized in the graft and there initiate a sequence of events which culminates in the graft's destruction. The meaning of "sensitization" in this context is uncertain, but some indirect evidence^{2,3} favours the possibility that the cells have on their surface specific antibody-like sites which are complementary to graft antigens. There is also one report of cells releasing haemolytic alloantibody at an early stage of the anti-graft reaction⁴. We have sought direct evidence for the existence of specific receptor-carrying cells by a modification of the cluster (rosette) technique^{5,6}.

Male and female CBA/H mice were grafted at 3–5 months of age with either allogeneic (A/H or A/Jax) or syngeneic skin from donors of the same sex. No differences between mice grafted with A/H and A/Jax skin, or between males and females, were detected, and the results were therefore pooled. Four to 27 days later recipients were killed. The brachial and axillary lymph nodes draining the graft area were removed and dissociated into a single-cell suspension, and the numbers of cells forming clusters with donor-strain and host-strain erythrocytes were determined for each mouse individually. Six million lymph node cells and 15×10^6 erythrocytes (both suspensions washed three times) were suspended together in 1 ml. of phosphate-buffered saline (pH 7.2), containing 5 per cent pooled CBA mouse serum, and were incubated overnight in siliconized 50×10 mm round-bottomed tubes at 6°C . During this time the cells settled. Half the cell-free supernatant was pipetted off, and the cells were resuspended by end-over-end rotation at 20 r.p.m. for 2 min. 0.05 or 0.1 ml. (approximately $3\text{--}6 \times 10^5$ cells) of each suspension was scanned at $\times 150$ magnification in a chamber made by supporting a 50×20 mm coverslip on a microscope slide with two narrow strips of polythene and 'Vaseline'. Possible clusters were verified at $\times 600$ magnification. The total number of nucleated cells remaining in the suspension was also determined. From these figures

Fig. 1. Typical homoclusters as seen after air-drying, methanol fixation and staining with Leishman. $\times 1,200$.

the number of cluster-forming cells in the pair of lymph nodes was calculated. Three tightly adherent red cells were taken as the minimum criterion for a cluster, but most comprised between seven and fifteen (Fig. 1). Cluster-forming cells were placed in one of three categories according to their apparent diameter in the counting-chamber: $< 8 \mu\text{m}$, $8-11 \mu\text{m}$, $> 11 \mu\text{m}$. Because individual mouse sera vary in their capacity to support cluster formation, samples from three large pools, which had been tested and found to yield comparable results, were used throughout the series of experiments.

In accordance with the usual terminology of transplantation, clusters formed with erythrocytes of the same species are called homoclusters. This category is divided into autoclusters (erythrocytes from the same individual), synclusters (erythrocytes from another individual of the same inbred strain) and allocusters (erythrocytes from a different strain).

Allogeneic grafts broke down in 8-10 days while evoking a three-fold increase in the cellularity of the regional lymph nodes. Syngeneic grafts were accepted permanently, but also elicited some ($< \text{two-fold}$) increase in cellularity. Fig. 2 shows the numbers of allocuster and syncluster forming cells (AFC and SFC) in the nodes of allografted mice. A mean background of 67 AFC and 69 SFC was found in the lymph nodes of normal untreated mice. An exponential increase in the AFC count was seen between the fourth and twelfth days, followed by a slow return towards the background level from the fourteenth day onwards. At the earliest stage there was a concomitant rise in the number of SFC, but it was smaller and of shorter duration. The increase in the numbers of AFC and SFC in the regional lymph nodes is not the result merely of localization of such cells from elsewhere in the body, for they increase also in distant lymph nodes (unpublished data). No significant rise in either AFC or SFC was seen in syngrafted mice (Fig. 3). Most (67-88 per cent) SFC and "early" AFC had the light microscope morphology of small lymphocytes. Larger cells of $8-11 \mu\text{m}$ diameter (most of the AFC on days 10 and 11) had strongly basophilic cytoplasm. No clusters were observed around cells which appeared to be macrophages. It seems probable that skin allografts induce the formation of SFC by presenting the recipient with antigen(s) structurally related, but not identical, to "self" constituents. By analogy with the results following immunization of artificially tolerant animals with antigens related to the tolerogen⁷⁻¹⁰, some cells reacting against an allograft would be expected to cross-react to some extent with self constituents.

This would by no means rule out the direct involvement of cluster-forming cells in the rejection of the graft. The cluster assay gives no information about the energy of interaction (affinity) between lymphocyte and erythrocytes. This may be higher with allogeneic than with syngeneic (or autologous) erythrocytes (a situation analogous to that which occurs when, for example, bovine serum albumin (BSA)-tolerant rabbits are immunized with dinitrophenyl-BSA¹⁰), and this difference may be crucial *in vivo*, ensuring effective localization of the cells in the graft.

Alloantibodies were first detected in the serum 8 days after grafting (unpublished results of R. G. Kinsky, H. S. M. and N. A. S.). By this time there was definite evidence of cells reacting specifically with donor-type erythrocytes (Fig. 2), and it is probable that they were progenitors of antibody-secreting cells. It is not known whether earlier SFC or AFC released any antibody molecules. Hildemann's⁴ results suggest that some complement-fixing antibodies may be released several days before such antibodies are detectable in the serum. Their reactivity with autologous erythrocytes was not

Fig. 2. Log_{10} numbers of AFC (\circ) and SFC (\bullet) in the draining lymph nodes of CBA mice grafted with A-strain skin (mean \pm s.e.). Broken lines indicate 95 per cent confidence limits for non-grafted controls. Points for day 0 are based on 28 mice, other points on 4-11 mice (median 6).

Fig. 3. Log₁₀ numbers of AFC (○) and SFC (●) in the draining lymph nodes of CBA mice grafted with syngeneic skin (mean ± s.e.). Broken lines indicate 95 per cent confidence limits for non-grafted controls. Points for day 0 are based on 28 mice, other points on 4–6 mice (median 6).

reported, but because their formation corresponded temporally with our SFC response they may have included autoantibodies.

It seems clear that the receptors on the lymphocyte surface for syngeneic or allogeneic erythrocytes are antibody-like molecules related to serum immunoglobulins, as has been shown for lymphocytic receptors for sheep erythrocytes¹¹. Elsewhere we present data in favour of this view, and discuss two possible functions of auto-reactive cells, one of which would give such cells a position of central importance in immunity^{12,13}. We also assume that AFC and SFC synthesize their own receptors and do not acquire them passively. The available evidence, especially the failure of other workers^{11,14–16} to demonstrate antibodies cytophilic for mouse lymphocytes, supports this view, but is not entirely conclusive.

Because an AFC/SFC response is detectable several days before rejection of a skin graft, the assay could possibly be adapted to give early warning of a rejection crisis in human transplant patients. Homocluster-forming cells are readily detectable in the peripheral blood of mice, although it remains to be seen whether the temporal pattern of response resembles that which is seen in the lymph nodes. Such a development would, however, depend on study of the effects of immunosuppressants on homocluster-forming cells and probably also on the use of nucleated target cells.

We thank Dr D. A. L. Davies of Searle Research Laboratories for a gift of A/Jax mice. This work was supported by grants from the Medical Research Council.

Lymphocyte Stimulation in Pigs: Evidence for the Existence of a Single Major Histocompatibility Locus, PL-A

IN those species which have been sufficiently studied there is evidence of a single major histocompatibility locus (man, mouse, rat, chicken) that plays a predominant part in graft rejection. We present evidence for the existence of such a major locus in pigs by using the mixed lymphocyte reaction^{1,2}.

The technique of culture used has already been described³. 5 per cent inactivated foetal calf serum and 10 per cent inactivated weaner pig serum were added to the medium. Maximum stimulation occurred between 48 and 72 h with significant depression later. The incorporation of ¹²⁵I-labelled 5-iodo-2'-deoxyuridine was used to assess stimulation in the cultures⁴.

In the first experiment, seven piglets, A, B, C, D, E, G and I, of the same litter, were tested in one-way stimulation. The results of these experiments are represented in Fig. 1A,B. The litter of seven piglets can be divided into four groups of identical siblings as follows:

The probability of the mixed cultures being different from the controls by chance only was calculated and taken as significant at $P < 0.05$.

In the second experiment, a litter of eleven piglets was tested. To simplify the task, it was decided initially to use the two-way reaction; the results allowed a probable decision as to which were the incompatible piglets. The non-stimulations could be the result of compatibility, or to the inhibitory effect of the large number of cells used, the latter having already been reported^{1,5}. To explore this possibility, one-way stimulations were performed between some of the non-stimulating piglets (Fig. 1C,D). Some apparent non-reactors in the two-way system showed a good stimulation in the one-way system where smaller numbers of stimulating cells were used. The litter could therefore be represented as follows:

A slight stimulation was, however, found between C and E. The existence of antigenic differences in the minor histocompatibility loci could account for this stimulation, for a similar situation has been found between two human siblings whose HL-A typing showed identity (unpublished results of D. V. and R. Harris). This indicates that "strong" differences at minor loci can account for an MLC reaction in siblings identical at the major histocompatibility locus in some instances of coincidence, for example of several non-HL-A antigens. Such a situation has also been found in the mouse⁶. Some "strong" reactions between "weak stimulators" could also be explained in the same way. ("Strong" and "weak stimulators" are defined by the number of stimulating cells which are necessary to obtain maximum stimulation. With "strong stimulators" a low dose of stimulating cells is sufficient; higher doses inhibit the reactions.) Groups

having the double chromosome difference should exhibit strong stimulation; but this was not always the case. Members of the same group reacted in different ways, some being "strong" stimulators and some "weak" when tested against a piglet of a different group. Antigenic differences determined by the other minor histocompatibility loci, in addition to the major one, could account for these results. On the other hand, one chromosome difference could involve varying numbers of strong antigenic differences which could account for these "strong" stimulations. The quantitative differences in the reaction should therefore be interpreted with caution and only as a possible indication of a haploid or diploid difference.

Our findings provide evidence that in pigs there is a major histocompatibility system analogous to that of other species that have been studied. Because the pig is much used in experimental surgery⁷ and typing sera are not yet generally available, matching by the MLC reaction could be used to obtain compatible pairs of recipients for grafting experiments, which was the purpose of this work. The method could also be used to obtain typing sera by cross-immunization between siblings

Studies on the HL-A Antigens of Human Lymphocytes: Inheritance in Clusters

A NUMBER of HL-A antigens are known to be present on human lymphocytes. We present here an interpretation of the genetic relationships between these antigens. The interpretation is based on an analysis of data collected in this laboratory.

Four hundred and twenty unrelated Australians were grouped by the cytotoxicity test for thirteen lymphocyte antigens. Not all of the subjects were tested for every antigen (Table 1). HL-A1, HL-A2, HL-A3, HL-A7, HL-A8, HL-A9 (LA4) and S Ly1 were each detected by a number of antisera so that the antigens could be identified beyond any reasonable doubt. Lc-20 (Walford) and S Ly2 were each identified by one antiserum only. HL-A5, 4a, 4b and 4c were difficult to define precisely and the reactions of each individual antiserum detecting these antigens were considered separately.

A computer was used to calculate the following parameters: antigen frequencies (Table 1), gene frequencies (Table 1), antigen associations (Fig. 1), and allelic relationships between the antigens. The gene frequencies (p) were calculated from the antigen frequencies (A) using the formula $p = 1 - \sqrt{1-A}$. The correlation coefficient (r), a measure of antigen association¹, was calculated using the formula¹ $r = \sqrt{\chi^2/n}$. The value of χ^2 was adjusted by Yates's correction.

The computer analysis helped to recognize allelic relationships between the antigens by compiling the frequency of cases in which the subjects were positive for three antigens. When this frequency was zero, no subject possessed more than two of the three antigens, indicating that the three antigens might be allelic to one another. None of the subjects tested was positive for more than two of the LA antigens or for more than two of the '4' antigens. Within the LA and '4' series the antigens were negatively associated with one another (Fig. 1). The LA and the '4' antigens seem therefore to be determined by two systems of multiple alleles.

Lc-20 was positively associated with HL-A1 and negatively associated with HL-A2, HL-A3 and HL-A9. S Ly2 was included in Lc-20. Consequently Lc-20 was related to the LA antigens. The 4a and 4b antigens were negatively associated with one another. These antigens are, however, complex and they may in fact be serological artefacts. S Ly1, HL-A5 and 4c seemed to be included in 4a, and HL-A7 and HL-A8 in 4b. Consequently 4a and 4b were related to the '4' antigens. The LA and '4' antigens were positively associated as follows: HL-A1 with HL-A8, HL-A2 with S Ly1, HL-A3 with HL-A7, S Ly2 with 4c. HL-A9, an LA antigen, seemed to be included in 4a, a '4' related antigen. HL-A1, an LA antigen, was nega-

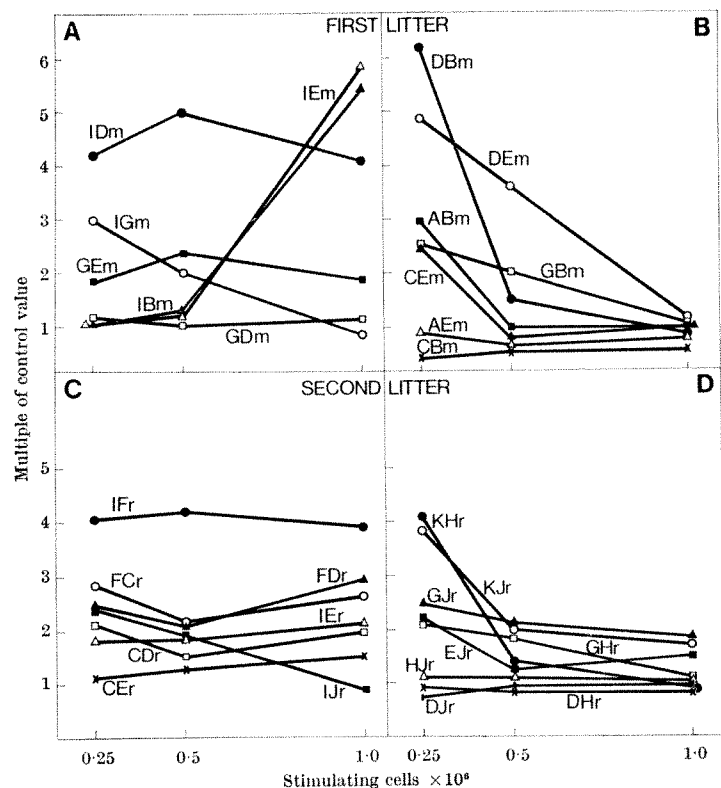

Fig. 1. One-way stimulation between piglets of the same litter. The stimulating cells were inactivated by mitomycin-C in the first litter and by X-rays in the second litter. The stimulation is expressed as multiples of the control, that is the sum of ¹²⁵I-iododeoxyuridine incorporation of both responding and stimulating (inactivated) cells which have been incubated separately for the same period of time as the mixed cultures.

having one haplotype difference. We suggest that the major histocompatibility locus in pigs should be called PL-A.

We thank Dr D. A. L. Davies and Professor R. Y. Calne for their helpful suggestions during this work, and Miss Elizabeth Garrett for technical assistance.

† S Ly indicates Sydney lymphocyte antigen; S Ly1 = KN-T12 (Kissmeyer-Nielsen).

tively associated with the '4' antigens, HL-A7 and S Ly1. HL-A2, an LA antigen, was negatively associated with 4b, a '4' related antigen. These associations were almost certainly a reflexion of the positive associations between the LA and '4' series already defined.

The concept of the LA and '4' series has been useful for defining the allelic relationships between the antigens within each series. But the statistically significant

associations and inclusions between the HL-A antigen series suggest that the antigens may be genetically determined not by two or more closely linked subloci, but rather by a series of allelic genes at the one chromosome locus. Each of these alleles could control several phenotypic expressions. For example, different alleles may determine each of the following pairs of antigens: HL-A1 and HL-A8, HL-A2 and S Ly1, HL-A3 and HL-A7, S Ly2 and 4c, possibly HL-A9 and a component of 4a.

The low power of tests of association in population studies¹ compared with family studies suggests that the former would detect only strong associations between antigens. The frequency of associations between the HL-A antigens in the Australian population (Fig. 1) implies that these antigens are strongly associated and reinforces the argument that they are inherited in clusters. This interpretation is analogous to Wiener's hypothesis² for the Rh system. Race and Sanger³ state that for the Rh system "we became embarrassed with hundreds of mutational sites" (regarded as subloci) "when previously we thought only three were needed". The Rh mutational sites are probably on the one gene rather than on a number of closely linked genes.

If the one gene has several mutational sites, the separation of antigens into allelic series could be the result of a series of mutations at the one position on the gene. Mutations at two or more such positions on the gene would give rise to two or more allelic series of antigens. If each gene determines an antigen in two or more allelic series, the antigens of these series would not be inherited separately but in clusters, as is so frequently seen with the HL-A antigen. Furthermore, no recombinations between

Fig. 1. Correlation coefficients between lymphocyte antigens (or antisera—see Table 1). The level of significance (P) of the correlation coefficient (r) is indicated as follows: $P > 0.05$: r is omitted from table; $0.05 \geq P > 0.01$: one asterisk above r ; $0.01 \geq P > 0.001$: two asterisks above r ; $0.001 \geq P$: no asterisk above r .

the antigens would be possible and indeed no absolutely convincing cases of recombinations between the Rh or the HL-A antigens have been reported.

The practical significance of this concept is that it predicts a number of genetically determined combinations of HL-A antigens. The recognition of these units of genetic information may facilitate HL-A antigen matching of recipients and unrelated donors before transplantation.

We thank Mr D. Rolls, University of Sydney, for writing the computer program; Dr H. V. Bashir, of this laboratory, and Dr J. H. Stewart, Sydney Hospital, for reading the manuscript; Dr M. Berah, Red Cross Blood Transfusion Service, Melbourne, for the antisera Hinchcliffe and Normington; Dr J. J. van Rood, Leiden University, for the antisera VR 1216 and VR 2708; and the NIH Serum Bank for the antisera Anderson, To/01/02, To/28/03, Kesler and Brewer. This work was aided by a grant from the Australian Institute of Urology.

Effect of 2-(α -Hydroxybenzyl)-benzimidazole and Guanidine on the Uncoating of Echovirus 12

2-(α -HYDROXYBENZYL)-benzimidazole (HBB) and guanidine have been shown to inhibit selectively the multiplication of picornaviruses¹. Both substances inhibit the appearance of a functional viral RNA polymerase², the replication of viral RNA^{3,4}, and the synthesis of viral coat protein⁴. While inhibition of synthesis of viral capsids seems to be a secondary phenomenon, probably a consequence of the failure of formation of viral RNA⁵, it is not clear whether the primary site of action of these compounds is principally the synthesis of viral RNA polymerase^{6,7}. As to the early steps of virus-cell interaction, it was shown that virus adsorption and penetration remain unaffected by HBB and guanidine^{4,8}, yet their effect on uncoating has not been determined. The period inhibitable by HBB and guanidine extends well into the exponential increase phase of the virus, thus covering the synthetic period of viral RNA polymerase and viral RNA, but it begins in the replication cycle at a time when synthesis of viral RNA polymerase and of viral RNA are not yet demonstrable^{3,4,8}.

Picornaviruses made photosensitive by incorporation of neutral red (NR) seemed to offer a possibility to investigate the uncoating process and whether it is affected by these inhibitors: previous studies on NR-poliovirus indicated that the dye is incorporated into the virus particle during virus multiplication; the virus particle thereby becomes photosensitive, but it loses its photosensitivity again after infecting cells⁹. This approach was taken in the following experiments.

Our test system consisted of echovirus prototype 12 (Travis) and primary rhesus monkey kidney cell cultures⁴. NR-echovirus 12 was prepared and its properties were determined. Echovirus 12 was grown for three passages in Eagle's minimal essential medium (MEM) containing 10 μ g/ml. NR. This operation, like any other involving NR-virus, was conducted under red light which was shown

Fig. 1. Kinetics of uncoating of echovirus 12 after incubation at 37° C. Cell monolayers were infected with 0.1 p.f.u. per cell of NR-virus. After 30 min at 2° C, the cells were washed with cold phosphate-buffered saline, overlaid with Eagle's MEM and incubated at 37° C. At the times indicated, assays were made for total and for photoresistant infective centres¹⁰. The number of photoresistant infective centres is expressed as a percentage of the total amount in respective cultures. In all samples, the total number of infective centres per plate was about 1.1×10^5 . At time 0 (end of adsorption), only one photoresistant infective centre was found, that is, it amounted to less than 0.01 per cent of the total. The number of photoresistant infective centres then rapidly increased and reached a maximum by 2 h, here 100 per cent of the total.

to be non-inactivating. The titre of various preparations was in the order of $0.5-1.0 \times 10^9$ plaque forming units (p.f.u.)/ml. By irradiation with white light for 10 min¹⁰ the infectivity was reduced by more than 10^5 times. RNA extracted from NR-virus by phenol⁴ was found infective and was no longer photosensitive. If mixed with NR, the RNA lost its infectivity by exposure to light, but fully retained it in the dark. On the other hand, no infective RNA could be extracted from NR-virus previously exposed to white light. Exposure of standard virus (not grown in the presence of NR) to NR and white light had no effect on its infective titre. These observations and those obtained with poliovirus⁹ suggest that the dye is incorporated into echovirus 12, that its RNA is the target of photodynamic inactivation and that during uncoating desensitization takes place by dissociation of dye and viral RNA. Accordingly, in the following experiments loss of photosensitivity of NR-virus after it had infected cells was taken as a measure of uncoating. The kinetics of uncoating of echovirus 12 after incubation at 37° C is shown in Fig. 1.

In the following experiment the effect of HBB (D-2-(α -hydroxybenzyl)-benzimidazole hydrochloride)¹¹ and guanidine hydrochloride on the uncoating of echovirus 12 was tested. Cells were pretreated for 20 min with either 0.1 mM HBB, 2 mM guanidine, or phosphate-buffered saline, and were then infected. The test was carried out in principle as described earlier, except that in respective culture media the indicated compounds were present until irradiation with white light took place. The percentage of uncoated virus was determined after incubation for 3 h at 37° C, a time when uncoating had reached its maximum in untreated controls. In order to make sure that the compounds were in fact inhibitory to the virus, sets of cultures with or without the compound were incubated for 8 h after the end of adsorption. This time corresponds to a single cycle of virus multiplication⁴. After collection, the virus materials were irradiated with white light to destroy input virus and were then tested

Table 1. EFFECT OF HBB AND GUANIDINE ON UNCOATING OF ECHOVIRUS 12

Treatment	Exposure to light	Infective centres per plate 3 h at 37° C	Virus yield (p.f.u.) per plate 8 h at 37° C
Untreated control	—	2.7×10^5	
	+	2.3×10^5	1.1×10^8
HBB, 0.1 mM	—	2.5×10^5	
	+	2.1×10^5	$< 1.0 \times 10^1$
Guanidine, 2 mM	—	2.2×10^5	
	+	1.8×10^5	1.2×10^8

for the yield of newly synthesized virus. The results are given in Table 1.

Although HBB and guanidine strongly inhibited the multiplication of echovirus 12 (reduction of virus yield by 10^6 times and more), they had no effect on the uncoating of the virus, because the percentage of photoresistant infective centres was similar in both treated and untreated groups. These results are compatible with kinetic studies on the multiplication of various picornaviruses in the presence of the inhibitors^{4,8}, but because guanidine inhibits the development of ultraviolet-irradiation resistance by poliovirus infective centres¹²—a Luria-Latarjet type of experiment—an event immediately following uncoating must be affected by guanidine. Further studies will reveal the nature of these biochemical events.

Crystal Structures of Dimers of Uracil and 6-Methyluracil

THERE is at present great interest in the chemical and biological effects of ultraviolet irradiation of nucleic acids. The possible correlation between the stereochemistry of the photoproducts and the biological consequences requires a detailed knowledge of the structures of these photo products. In addition to the methods of nuclear magnetic resonance^{1,2}, mass spectra³, topochemistry⁴⁻⁷ and chemical analysis⁸⁻¹⁰, X-ray analysis is most conclusive. Consequently, crystal structure analyses have been performed on an adduct of thymine¹¹⁻¹³ and a trimer of thymine (unpublished) in addition to the *cis-syn*¹⁴⁻¹⁶, *cis-anti*¹⁷ and *trans-anti*^{18,19} cyclobutyl dimers of uracil and thymine derivatives. The analyses of various dimers show remarkable agreement in bond lengths and angles of the molecules even though the packing and hydrogen bonding, if any, are quite different for the various materials. The *cis-syn* and *cis-anti* forms all have a puckered four-membered ring with a dihedral angle $\sim 155^\circ$ except for the *cis-syn* photoproduct from 1,1'-trimethylene bis-thymine where the trimethylene bridge seems to force the cyclobutyl ring into a planar configuration¹⁶. The two structure determinations of the *trans-anti* form showed that the molecules themselves have a centre of symmetry and consequently the four-membered rings must be planar.

Fig. 1. The molecular structure of *cis-anti* U=U.

Two additional structure determinations are reported here. One is the *cis-syn* photodimer of 6-methyluracil crystallized with a molecule of water. It is unusual in that it is the first structure analysis of a hydrated form. The other is the *cis-anti* U=U, which results from the crystallization of U₃, a trimer of uracil²⁰. Apparently, U₃ has the same properties as the thymine trimer (T₃ or PT₃) (ref. 21), that is, some characteristics of the pyrimidine adducts, the photoreversibility of the pyrimidine dimers and the instability of a thymine photohydrate. But U₃ is much more unstable than the corresponding T₃. Although the structure of thymine phototrimer has now been established, attempts are being made to establish the structure of U₃.

To prepare *cis-syn*-6-methyluracil dimer (6MU=6MU), an aqueous solution of 6MU (2 mM; 5 l.) was irradiated in a frozen state for 2 h (ref. 22). In these conditions, 20 per cent dimerization was observed. After being thawed, the irradiated solution was evaporated until dry. The residue was taken up in a small volume of hot water and was applied to a 2 × 50 cm column of Dowex ('50W-X12', H⁺ form, 100-200 mesh). The column was eluted with distilled water. The first 200 ml. eluants having end absorption were combined as the "dimer fraction". This solution was concentrated under reduced pressure to 25 ml. and, after it had been allowed to stand at 5° C overnight, large colourless cubic crystals formed. This material was converted to 6MU on irradiation with 254 nm light in water. It is, however, stable in 2 M NaOH and in 6 M HCl. The *R_f* values of this compound are 0.38 (0.70 for 6MU) in *sec*-butanol and water (50:20); 0.25 (0.54) in *n*-butanol, acetic acid and water (80:12:30); 0.41 (0.64) in *tert*-butanol, methyl ethyl ketone, formic acid and water (40:30:15:15) and 0.40 (0.57) in *tert*-butanol, methyl ethyl ketone, concentrated ammonia and water (40:30:15:30) respectively.

cis-anti-Uracil dimer (U=U) was prepared according to the method reported previously for the U₃ (trimer of uracil) by the irradiation of uracil in ice²⁰. The conditions used for the crystallization of U₃ at boiling water temperature caused it to decompose to *cis-anti* U=U.

X-ray diffraction data for both crystals were collected photographically, along two axes, with the multiple-film, equi-inclination Weissenberg technique. Cell parameters and other data are listed in Table 1. Each structure was solved directly by the symbolic addition procedure for phase determination²³. Atomic coordinates

Fig. 2. The stereodiamgram of a unit cell of 6MU=6MU crystals.

(available on request) and anisotropic thermal factors were refined by least-squares methods and hydrogen atoms were located by means of difference maps. The agreement between observed and calculated structure factors is 9.9 and 10.6 per cent for the U=U and 6MU=6MU compounds, respectively.

The molecule of the *cis-anti* photodimer of uracil (Fig. 1) possesses very nearly a two-fold rotation axis, although none is required by the space group symmetry. The cyclobutane ring is puckered with a dihedral angle of 150°. The two uracil residues are rotated with respect to each other by 21° (torsion angles about the C5-C6' and C5'-C6 bonds). Each uracil residue has seven atoms which are coplanar to within 0.07 Å, while C6 and C6' are 0.38 and 0.35 Å out of the planes of the respective uracil residues. In every respect, the molecular geometry of the *cis-anti* dimer of uracil is very similar to that of the *cis-anti* dimer of 1,3-dimethylthymine¹⁷. The molecular environment in the crystal is different, however, in that the 1,3-dimethylthymine dimer cannot make any hydrogen bonds, whereas each dimer of uracil participates in eight NH...O intermolecular hydrogen bonds which range from 2.83 to 2.97 Å. The efficient hydrogen bonding scheme accounts for the high density, 1.70 g/cm³, in the crystal.

The *cis-syn* photodimer of 6-methyluracil with one molecule of water of crystallization can be compared with the anhydrous crystal of the *cis-syn* photodimer of uracil¹⁵. Again, bond lengths and bond angles in the two molecules are very similar. The cyclobutyl ring is puckered, but it is significantly flatter than in the anhydrous U=U. The dihedral angles in the cyclobutyl ring are 162° and the two uracil residues are rotated with respect to each other by 16.5° (torsion angles about C5-C5' and C6-C6') as compared with dihedral angles of 155° and torsional angles near 24° in the anhydrous crystal. Seven atoms in one of the uracil residues are coplanar within ±0.028 Å with C6 displaced 0.28 Å out of the plane, comparable with the configuration in the *cis-anti* U=U. The other uracil residue is composed of two planar units with a fold along the N3'...N6' line having a dihedral angle of 168.5°. As observed previously, there is little difference in the bond lengths and angles in the various photodimers which have been studied, but subtle differences in the skewness of the cyclobutyl ring and the deviations from planarity in the uracil or thymine residues are observed.

The fact that the crystals of 6MU=6MU contain the water molecules may be particularly interesting because it may correlate with the anomalous spectral data in

nuclear magnetic resonance and infrared for this photodimer (unpublished results). The stereodiamgram in Fig. 2 shows the contents of one unit cell. It is apparent that the dimers align themselves in rows in such a manner as to create continuous channels (along the *a* direction of the unit cell) for the water molecules. Each water molecule is hydrogen bonded to three different dimer molecules forming two OH...O bonds at 2.84 and 3.01 Å and one O...NH bond at 2.90 Å.

The four dimer molecules illustrated do not form hydrogen bonds with each other but they do form NH...O bonds with dimer molecules in adjacent cells.

Is Retinal-Phosphatidyl Ethanolamine the Chromophore of Rhodopsin?

SEVERAL laboratories have reported the presence of the Schiff base of retinal and phosphatidyl ethanolamine (retinal-PE) in bovine rod outer segments¹⁻³. Poincelot *et al.*³ claim that this compound is the chromophore of rhodopsin. Heller found only traces of phospholipid in purified bovine rhodopsin⁴, however, and presented evidence that retinal is attached directly to opsin in a substituted

aldimine linkage⁵. Hall and Bacharach⁶ injected frogs with ³²P and found large amounts of radioactivity in rod phospholipids, but none in purified rhodopsin. The purified rhodopsins of Heller^{4,5} and Hall and Bacharach⁶ had an absorption maximum at 500 nm and could be bleached by light. We recently determined the molar concentration of retinal-PE in bovine rods and compared it with the molar concentration of rhodopsin. We present here our preliminary findings.

Bovine rods were prepared by the common flotation-sedimentation centrifugation procedure using 37 per cent sucrose in 0.067 M phosphate buffer (pH 7.0). The rods were lyophilized and stored at -20° C in a light-tight desiccated container. Two preparations of rods were used in this study and are designated ROS 1 and ROS 2.

A known weight of dry rods was taken up in a known volume of 2 per cent aqueous digitonin and the spectrum between 240 nm and 650 nm was recorded. Absorbance at 500 nm was determined from the difference spectrum, and the molar concentration of rhodopsin was calculated from Beer's law ($A = \epsilon \cdot c \cdot l$). The data of Table 1 are in μ moles of rhodopsin per mg dry rods, calculated using molar extinction coefficients of Wald and Brown⁷ (40,600) and Heller⁴ (23,100). Differences in the rhodopsin concentrations for the two preparations can be explained by a higher concentration of protein in ROS 1. The A_{280}/A_{500} ratio was 4 in ROS 1 and 2.7 in ROS 2.

Phospholipids were extracted in the dark from known weights of dry bovine rods with anhydrous chloroform:methanol (2:1) made $10^{-3.5}$ M with anhydrous HCl gas. (Only about half of the lipid-phosphorus is removed from rods if chloroform is omitted from the extraction solvent. According to Poincelot *et al.*², no imine exchange occurs in model Schiff bases extracted in methanol made $10^{-3.5}$ M with HCl gas so that none should occur during this extraction.)

The retinal-PE content of the extracts was determined by two different procedures. In the first, the phospholipids while still in the extracting solvent were immediately hydrogenated over platinum oxide, converting the unstable Schiff base to a stable secondary amine. The reduced retinal-PE was separated from the other phospholipids by thin-layer chromatography and its phosphorus content compared with that of the total phospholipids. From the known molar concentration of phospholipids in the rods, the amount of retinal-PE (μ moles/mg dry rods) was calculated (Table 1).

In the second procedure, the rods were extracted in a known volume of the acidic solvent. The insoluble proteins were sedimented by centrifugation and the clear supernatant was removed and scanned. The molar extinction coefficient of synthetic retinal-PE had been previously determined to be 31,300, and this value was used to calculate the molar concentration of retinal-PE in the rods from Beer's law.

Table 1. CONCENTRATION OF RETINAL-PE AND RHODOPSIN IN BOVINE ROD OUTER SEGMENTS

Sample	Rhodopsin μ moles/mg dry rods		Retinal-PE μ moles/mg dry rods	
	ϵ (Wald)	ϵ (Heller)	P assay	Spectral assay
ROS 1	3.1×10^{-3}	5.4×10^{-3}	2.5×10^{-3}	2.7×10^{-3}
ROS 2	4.3×10^{-3}	7.5×10^{-3}	1.5×10^{-3}	1.9×10^{-3}

The similarity in the values for the retinal-PE content determined by the two procedures indicates that the numbers in the table are accurate estimates of the content of this lipid in bovine rods. Clearly the molar concentration of retinal-PE in bovine rods is not as high as that of rhodopsin, and it is therefore doubtful that it serves as the chromophore of rhodopsin, as claimed by Poincelot *et al.*². We are not suggesting that retinal-PE does not participate in the visual process. Its concentration in rods is such that it could serve to store 11-*cis*-retinal and function as a retinal "donor" in the regeneration of rhodopsin. This is now being tested.

A "Deep Sea Rhodopsin" in a Mammal

In a broad sense the absorbance spectra of the rhodopsins of fishes seem to vary to suit the spectral energy distributions of the lights reaching them through the water¹⁻⁶. Thus bathypelagic fishes, living in an environment where the ambient daylight (and the light from bioluminescent organisms) is maximal between 460 and 490 nm⁷, have rhodopsins of λ_{\max} between 472 and 487 nm (refs. 1-5). Similarly, coastal fishes, which live in light environments with peak radiation between 490 and 550 nm⁷, have rhodopsins that range correspondingly in λ_{\max} between 495 and 512 nm (refs. 3-5, 8).

It interested us to know whether aquatic mammals showed similar modifications, and Dr J. Everson of the British Antarctic Survey was fortunately able to obtain for us the eyes of an elephant seal *Mirounga leonina* Linn. and a Weddell seal *Leptonychotes weddelli* (Lesson).

The two seals were shot near the Survey Base (Signy Island) on moonless nights in June (elephant seal) and October (Weddell seal) of 1965. The eyes were removed at the Base and stored there in darkness in a deep-freeze until they were eventually sent to the Institute of Ophthalmology, London, where we processed them for their visual pigments in March 1969.

The retinas, one from each animal, were first washed in pH 7.0 buffer and then shaken with 2 ml. portions of 35 per cent sucrose solution to obtain suspensions of the photoreceptor outer limbs⁹. This procedure was repeated until no further yields of receptors were obtained, four suspensions being necessary for the elephant seal's retina and six for that of the Weddell seal. After precipitation of the photoreceptors they were bulked, dried in a vacuum desiccator and treated with 3 ml. portions of petroleum ether (b.p. 50°-60° C) until no more yellow pigment was extracted (nine extractions for the elephant seal and seven for the Weddell seal). The visual pigments were then extracted, each with 1 ml. of 3 per cent digitonin solutions. The yields of pigments from the two species were similar, that from the elephant seal having an absorbance maximum (1 cm path) of 0.96 (at about 485 nm) and that from the Weddell seal a maximum of 0.94 (at about 495 nm). Re-extraction of the residues with further 1 ml. portions of the digitonin solution yielded only a little more pigment.

Samples of the two extracts, after suitable dilution and addition of hydroxylamine, were examined by the partial bleaching technique (two bleachings at 600 nm, and a terminal bleach with "white" light filtered through a Wratten No. 15 filter). Both species were found to have

Fig. 1. Difference spectra of the two seal pigments in the presence of 0.02 M hydroxylamine (actual ΔA_{\max} = 0.49 (elephant seal) and 0.45 (Weddell seal) pH 8.6). Note that λ_{\max} for the elephant seal pigment is 485–486 nm ("deep sea rhodopsin") and that for the Weddell seal is 495–496 nm ("terrestrial and coastal water rhodopsin"). The product band in both cases (λ_{\max} = about 370 nm) is characteristic of the oxime of retinal.

essentially homogeneous rhodopsins with λ_{\max} = 495–496 nm in the Weddell seal, and λ_{\max} = 485–486 nm in the elephant seal (Fig. 1). Thus the rhodopsin of the Weddell seal resembles those typically found in coastal water fishes and terrestrial mammals, while the rhodopsin of the elephant seal resembles those of deep-sea fishes.

The Weddell seal is a south Antarctic species that lives near the coast or ice. The caval sphincter (that on the posterior vena cava, anterior to the diaphragm), which is associated with the diving habit in mammals, is not particularly well developed in this species¹⁰. Its teeth—and stomach contents—indicate that it feeds chiefly on fishes that are not bioluminescent¹¹.

The elephant seal, on the other hand, has a sub-Antarctic distribution and, save for the breeding period, lives a pelagic life (about which little is known) in deeper water¹². Judged by its very powerful caval sphincter it is capable of diving to great depths¹⁰. Its teeth, and stomach contents, suggest that it feeds on squids¹².

Thus, superficially at least, there seems to be a correlation between the ecology of these seals and their rhodopsins. In spite of its weak caval sphincter, however, the Weddell seal often dives 200 m or more into the exceptionally clear waters beneath the Antarctic ice¹³. Many pelagic fishes that are caught at comparable depths have "deep sea rhodopsins" but, as we have seen, the Weddell seal has not. This makes it reasonable to speculate that the "deep sea rhodopsin" of the elephant seal is an adaptation not so much to the ambient light of solar origin as to that emitted by the bioluminescent squids on which it feeds.

Reversible Visual Pigment Changes in Tadpoles exposed to Light and Darkness

THE visual pigments of many amphibian larvae are mixtures of rhodopsin and porphyropsin, the latter usually, but not always, predominating¹⁻³. During the metamorphic climax, the porphyropsin is wholly discarded and the rhodopsin emerges as the characteristic pigment of the adult retina. I describe here a hitherto unsuspected reaction of the larval retina: as in fishes⁴⁻⁸, the balance between rhodopsin and porphyropsin can be altered by exposure to light and darkness. The phenomenon does not seem to be connected with the metamorphic process.

Fig. 1 illustrates difference spectra of the visual pigments extracted from *Rana pipiens sphenocephala* tadpoles. These animals started out with 39 per cent porphyropsin and 61 per cent rhodopsin. The difference spectrum of this mixture is shown by the dashed curve. A group kept in darkness for 26 days had a blue-displaced spectrum representing pure rhodopsin, while another group kept in continuous light over the same period had a red-displaced spectrum representing as much as 69 per cent porphyropsin. The system differs from fishes, where darkness favours porphyropsin while light favours rhodopsin⁴⁻⁸.

In this experiment, there was no difference between the metamorphic levels attained by the light and dark groups, even though the latter lacked the larval visual pigment. Moreover, another experiment with *R. catesbeiana* tadpoles revealed that, unlike the results of metamorphosis, the effects of light and darkness are reversible. In this respect the situation resembles that observed in fishes. Initially, the tadpoles (average Taylor-Kollros⁹ stage X) had 84 per cent porphyropsin (compare Wilt¹⁰). They were divided into two groups. Group A was placed in a light-tight cabinet, group B under continuous illumination. After 1 month the porphyropsin of group B had remained almost unchanged at 88 per cent, but had dropped to 40 per cent in group A (Fig. 2). The light conditions were then reversed. Group B was transferred to the dark, when the porphyropsin diminished to 44 per cent after 1 month; and group A was transferred to the light, when the visual pigments reverted to 88 per cent porphyropsin and 12 per cent rhodopsin. At all times, the average Taylor-Kollros stages of the tadpoles sampled lay between IX and XI.

Apparently, prolongation of the period spent in light or darkness did not induce any further shifts of pigment composition (Fig. 2). Preliminary analyses have indicated,

Fig. 1. Difference spectra of visual pigments from *Rana pipiens sphenocephala* tadpoles kept in light and darkness. Extracts in digitonin were prepared from whole eyes, and contained 10 mM hydroxylamine at pH 7. ---, Twelve specimens from initial batch; ○, eleven specimens kept unfed for 26 days under continuous illumination from a tungsten lamp (186 ft candles at water surface); ●, ten specimens kept unfed in complete darkness for the same period of time. The tadpoles originated from the Carolina Biological Supply Co. (July 1969).

Fig. 2. Visual pigment changes in *R. catesbeiana* tadpoles kept in light and darkness. Group A (●—●) were placed in darkness for 4 weeks, then switched to continuous illumination (186 foot candles at the water surface); conversely, group B (○—○) were placed initially under continuous illumination for 4 weeks, then switched to darkness. Figures in parentheses represent the numbers of tadpoles in each sample. The tadpoles originated from the Carolina Biological Supply Co. (October, 1969).

however, that there is marked individual variation in the "dark" animals (but not in the "light" ones), so there is some uncertainty in this result which is based on only three specimens.

Is the effect under endocrine control? Thyroxine induces a shift towards porphyropsin in some salmonids¹¹, but it is not clear whether this hormone is responsible for visual pigment changes caused by light and darkness^{7,8}. In amphibian larvae thyroxine has the reverse action^{10,12}, so that one explanation for these observations would be an increase in thyroid activity in darkness. Alternatively, darkness might decrease the output of prolactin, a general antagonist of thyroid hormone during amphibian development¹³. An increase in thyroid activity (or decrease in prolactin) sufficient to alter retinal pigment composition should, however, be accompanied by accelerated and irreversible metamorphosis^{10,12}, yet the "dark" tadpoles were no further advanced than the "light" ones. This indicates that the light and dark-induced visual pigment shifts were not mediated by thyroxine.

Adaptation in the Isolated Rat Retina

THE isolated retina is a useful preparation for studying many aspects of visual sensitivity. Photochemical changes following exposure to light may be studied directly, and concomitant electrical events may be monitored with gross and micro-electrodes. The photopigment is also not appreciably regenerated during an experiment, and loss of sensitivity following light exposure shows a clear relationship to visual pigment concentration.

Dowling¹ has shown a relationship between rhodopsin concentration and the logarithm of visual sensitivity by using a constant amplitude ERG response as a measure of retinal sensitivity. Rushton²⁻⁵, using psychophysical methods and reflective densitometry, has demonstrated the relationship in man. This has also been confirmed in the isolated rat retina⁶. Donner and Reuter^{7,8} have used ganglion cell responses as a criterion of retinal sensitivity, and they have demonstrated photopigment regeneration in this preparation. They have also related the rate of regeneration of rhodopsin to the recovery of sensitivity.

Baumann⁹ studied the relationship between the ERG and rhodopsin concentration in the dark-adapted isolated frog retina, and also found a linear relationship between log sensitivity and rhodopsin concentration. Baumann and Scheibner¹⁰ showed, however, that this relationship was non-linear when ganglion cell, rather than ERG responses, were used to determine sensitivity. They emphasized that the spatial characteristics of the stimulus might be responsible, in part, for this discrepancy, because large test spots may depress sensitivity because of lateral inhibition which affects ganglion cell, but not ERG, sensitivity.

Using large spot stimuli, we have shown¹¹ that there is a linear relationship between ERG and ganglion cell sensitivity. But Brown and Rojas¹² have shown that the rat retina contains two types of ganglion cell receptive fields: those having centres with antagonistic surrounds, and those without surrounds. Brown¹³ has tentatively related two specific dendritic configurations to these functional types. To find out if our earlier findings relating ERG and ganglion cell sensitivity need to be reinterpreted, we have repeated these experiments using various stimulus conditions.

The techniques used for isolating the rat retina and the perfusing medium have already been described^{6,11}. Rats were sometimes anaesthetized with intraperitoneal 'Nembutal', but about half of the experiments were conducted following decapitation without prior anaesthesia. In both cases, stimulus-induced responses were unaffected, with fairly constant thresholds from unit to unit. But 'Nembutal' tended to reduce the frequency with which spontaneously active units were found. An insulated platinum-iridium micro-electrode was introduced through a dual channel perfusion chamber from above, using a micro-manipulator. Electrode tips were 0.5–1.0 μ m in diameter. Impedance in saline was 100–500 k Ω at 1 kHz. The retina, illuminated from above, was mounted with receptors up, and the stimuli were presented from below. Electrical responses were led from a cathode-follower pre-amplifier to two Tektronix 122 amplifiers. One amplifier was set to a band width of 801 kHz, and the other to 0.2–20 Hz, to record the ganglion cell and the ERG responses, respectively. The amplifiers were connected to separate channels of a four-beam Tektronix 564 storage tube oscilloscope. Another beam displayed the output of a photocell which indicated the stimulus. A Polaroid camera was used to photograph the responses and ganglion cell responses were monitored with a Grass audio amplifier and loudspeaker.

The optical stimulator used a high pressure xenon arc lamp (Bausch and Lomb) with a regulated power supply. The light from this source was condensed and then collimated with a series of lenses. An electromagnetic

Fig. 1. Two oscillograms showing simultaneously recorded ERG and ganglion cell responses. The tracings on the left show a single ganglion cell action potential in response to the stimulus (on cell). The tracings on the right show responses to a stimulus 0.6 log units brighter than that on the left. Several action potentials are shown, but the ERG threshold has not yet been reached.

shutter ('Uniblitz') was used to present stimuli of 0.5 s duration. Repetitive stimulation could be presented with the aid of a Tektronix 161 waveform generator, 162 pulse generator, and 160 power supply, synchronized to trigger. Metal film neutral density filters (Optics Technology) and a pair of circular wedge filters (Kodak) mounted on a Gebhardt holder were used to attenuate the beam. Small spots and annuli could be presented to the retina by interposing two plastic disks with various sized apertures and black dots. These disks were attached to a calibrated mechanical stage with vernier scale, which permitted movements in the plane projected to the retina. The spot was $100 \pm 20 \mu\text{m}$, as measured at the retina. Another similar optical channel with a tungsten source enabled a second small spot of light to be projected on the retina. This second channel, combined with the first at a beam splitter, was also used to present large spot stimuli for ERG responses.

Thresholds for ERG and ganglion cell action potentials were determined in conditions of full dark adaptation, and also after 10 min of dark adaptation following 5 min exposures to light of increasing intensities. Usually three or four separate exposures to the adapting light were given, each of bleaching intensity⁶. The last and brightest light adaptation was repeated to ascertain that bleaching was, in fact, complete, with no further changes in sensitivity. Most experiments took 2–3 h.

Single ganglion cells were usually encountered after several random prings with the micro-electrode. This was advanced slowly through the retinal thickness with the aid of a micromanipulator, while presenting intermittent, dim stimuli. When expanded on the horizontal (time) axis, the uniform action potentials were almost always biphasic, indicating that the responses were being recorded extracellularly from the ganglion cell body.

Fig. 2. Ganglion cell action potential in response to cessation of light stimulus (off cell).

The range of adaptation for ganglion cell responses in these experiments was 6.5 ± 0.5 log units. The thresholds for ERG *b*-waves of 10–25 μV were slightly higher (0.5–0.8 log units). Usually a single action potential was used as the criterion for the ganglion cell threshold, while a constant amplitude *b*-wave was used for the ERG threshold. Typical ganglion cell responses for both 'on' and 'off' cells are shown in Figs. 1 and 2.

In a typical experiment, there was good agreement between ganglion sensitivities obtained with both large

and small stimuli. Data combined from six experiments are plotted in Fig. 3. Here, two lines are illustrated, each providing a best fit for large spot and small spot data. The difference in slopes of these two lines is probably negligible.

Table 1. RECEPTIVE FIELDS OF RAT RETINAL GANGLION CELLS

	On-centre	Off-centre	Units with surrounds	Units without surrounds
Living rat (Brown and Rojas ¹²)	23	28	23	28
Isolated retina (present study)	25	5	1*	30

* On/off unit.

Most ganglion cells encountered were of the 'on' type. All except one had no surround. These results are at variance with those obtained from the living rat by Brown and Rojas¹² (Table 1). The data were obtained by determining threshold sensitivities at varying distances from the centre of the field (point of maximum sensitivity). The progressively decreasing sensitivity away from the centre is probably caused by scatter of the stimulus into the centre. These data were obtained in full dark adaptation, but similar curves were also obtained with partially dark-adapted and with light-adapted units.

The receptive field organization of the lone unit with a surround is shown in Fig. 4. This unit was an 'on-off' cell, with 'off' responses elicited by stimuli falling on its centre, and 'on' responses from stimuli in the surround (including annular stimuli). This cell was encountered after the preparation had been partially light-adapted, but its organization did not change in the hour during which it was being studied, with further changes in adaptation.

These experiments confirm our earlier findings, in which only large stimuli were used. The relationship between rhodopsin concentration and the logarithm of retinal sensitivity, whether determined by the ERG or the ganglion cell, is linear. This agrees with unpublished findings of Dowling and Ripps in the all-rod retina of the skate in which ganglion cell responses to small stimuli were compared with spectrophotometric data obtained by rapid scanning of the visible spectrum.

The discrepancy between the findings of our study and those of Brown and Rojas, regarding the prevalence of ganglion cell receptive fields with antagonistic surrounds, is disturbing, and not easily resolved. One possible explanation is that units without surrounds were preferentially selected because of the electrodes used, or because

Fig. 3. A comparison between ganglion cell and ERG sensitivity: combined data from six experiments. Both large and small spots were used to determine ganglion cell sensitivity. Two lines providing a best fit for the large spot and the small spot data points are indicated. The solid line best fits the small spot data and the interrupted line best fits the large spot data. The difference in slopes between these two lines is probably negligible. *, Same data points for large and small spots.

Fig. 4. Receptive field organization of a ganglion cell of the isolated rat retina. A single unit was found which showed centre surround organization. A diffuse stimulus produced an on response in this cell. A small spot presented in the region of the recording microelectrode produced an off response. An annular stimulus or a slightly eccentric spot produced an on-off response.

of the preparation. Another explanation might be that of sampling error. We know of no way to resolve the matter at the present time.

Enzyme Flexibility in *Drosophila melanogaster*

POLYMORPHISMS for genetically determined enzyme variants have been reported in humans¹, *Drosophila*² and several other groups of organisms, but there is no adequate explanation for their occurrence. Genetic polymorphisms can be maintained in numerous ways³, but Haldane⁴ and Mayr⁵ have emphasized that geographical

or temporal changes in the environment could place a premium on metabolic flexibility and that selection for heterozygotes or alternating selection for different homozygotes might establish the necessary enzyme heterogeneity in the population.

Natural populations of *Drosophila melanogaster* are often polymorphic for two electrophoretic variants of alcohol dehydrogenase (*Adh*^F and *Adh*^S) each determined by a single genetic locus⁶, but in most laboratory populations investigated the *Adh*^F gene has been fixed. Our evidence shows that the various forms of alcohol dehydrogenase have different thermolabile properties and are differentially affected by the presence of ethanol in the culture medium, which suggests that variation in temperature, strains of yeasts and their conditions of growth should be considered as environmental factors that may be relevant to the maintenance of this polymorphism.

Homogenates of twenty third instar larvae in 1 ml. 0.05 M orthophosphate buffer (pH 7) of each of the three genotypes *Adh*^F/*Adh*^F, *Adh*^S/*Adh*^S and *Adh*^F/*Adh*^S on a common genetic background were centrifuged at 30,000g for 20 min. The supernatants were assayed for alcohol dehydrogenase activity in a Unicam 'SP 800' spectrophotometer by following the increase in absorbance at 340 mμ after addition of the enzyme extract to a solution containing nicotinamide adenine dinucleotide (NAD) and isopropanol. Total protein content of each extract assayed was determined by the Folin method as modified by Lowry *et al.*⁷.

Third instar larval extracts of *Adh*^F homozygotes have a higher enzyme specific activity than extracts from *Adh*^S homozygotes (Table 1). In assays at 25° C, enzyme activity in extracts of *Adh*^F/*Adh*^S heterozygotes is intermediate between the activities of the two parental extracts. Similar results have been described for extracts of adult flies⁸.

After the enzyme assays the larval extracts of the three genotypes were kept for 10 min in a 40° C water bath and the enzyme activity remaining was measured. Following this heat treatment, enzyme extracts from the *Adh*^S homozygote are more stable than the extracts from the *Adh*^F homozygote or from the *Adh*^F/*Adh*^S heterozygote (Table 1). Heat-treated extract from heterozygotes, however, has a higher specific activity than extracts from either of the two homozygotes.

Table 1
Mean specific activities*

<i>Adh</i> genotypes	Larval extract	s.d. \bar{z}	Heat-treated extract	s.d. \bar{z}	Loss of activity (per cent)	Culture medium with 6 per cent ethanol	s.d. \bar{z}	Increase in activity (per cent)
<i>Adh</i> ^F / <i>Adh</i> ^F	8.5	0.33	1.2	0.092	85.9	12.4	0.57	45.8
<i>Adh</i> ^S / <i>Adh</i> ^S	2.9	0.13	1.5	0.188	45.6	3.5	0.23	20.7
<i>Adh</i> ^F / <i>Adh</i> ^S	5.4	0.32	2.0	0.108	61.6	6.8	0.28	30.8

* Each value is the mean of eight separate assays. Enzyme assays of treated and untreated extract were run concurrently.

Homogenates of single third instar larvae homozygous for either *Adh*^F or *Adh*^S normally show three major bands and two minor bands after electrophoresis on polyacrylamide gels and subsequent tetrazolium staining. The major bands designated F₁, F₃ and F₅ in *Adh*^F/*Adh*^F (S₁, S₃ and S₅ in *Adh*^S/*Adh*^S) from the most anodal, are also present in *Adh*^F/*Adh*^S heterozygotes together with a further three bands which occupy positions in the gel intermediate between the corresponding parental bands. To test the effect of the heat treatment on the *Adh* phenotypes, electrophoresis on polyacrylamide gels was carried out on heat-treated extracts from each of the three genotypes. In extracts from *Adh*^F and *Adh*^S homozygotes the F₃ and S₃ bands respectively were absent and the F₁ and S₁ bands were very faint confirming previous work⁹. Two distinct bands were found in gels run with heat-treated heterozygote extract and these corresponded to bands F₃ and S₃. It has previously been shown^{10,11}

that the F_1 and F_3 bands represent enzyme bound to NAD and the heat stability in a gel of the F_3 moiety is enhanced after dialysis against NAD when the F_3 band is converted to F_2 and F_1 . Presumably the three bands in *Adh^S* homozygotes are also explicable in terms of NAD binding to the enzyme and bands S_1 and S_3 will be more heat stable than band S_2 as the bound NAD will stabilize the enzyme. It is not yet known whether the three extra bands found in heterozygotes also result from differing degrees of NAD binding to the enzyme; some of these bands may represent hybrid enzyme molecules. Nevertheless, the NAD bound enzyme present in heterozygotes appears to be more heat stable than the NAD free enzyme.

To determine whether the level of alcohol dehydrogenase in the three genotypes was affected by the food medium on which the *Drosophila* were cultured, eggs were collected and transferred to a dead yeast/glucose medium supplemented with 6 per cent ethanol. Samples of third instar larvae of the three genotypes cultured on this medium were assayed for alcohol dehydrogenase activity. With isopropanol as the assay substrate, there is a differential increase in enzyme activity in extracts of the three genotypes, *Adh^F* homozygotes having the largest increase (Table 1). It therefore appears that environmental changes produce differences in enzyme activities in different *Adh* genotypes. There is marked genotype environment interaction.

Experiments are being carried out to investigate whether the different levels of alcohol dehydrogenase activity in *Drosophila* have any adaptive significance. Preliminary results suggest that they have. Four bottle cultures were started with the alleles described at a gene frequency of 0.5 *Adh^F* and maintained at 25° C by mass transfer every 2 weeks. The standard dead yeast/glucose culture medium was supplemented with 6 per cent ethanol for two of the populations. After eighteen generations the gene frequency in the two control populations had not changed, whereas in the two ethanol supplemented cultures the gene frequencies of *Adh^F* had increased to 0.73 and 0.82.

In natural habitats yeasts are an important factor in the ecology of *Drosophila* species^{12,13} and there is probably considerable variation in the amounts of ethanol produced by yeast fermentation in *Drosophila* habitats. It is possible that the rate of ethanol oxidation in *Drosophila* is not directly related to the level of alcohol dehydrogenase activity. A polymorphism exists in human populations for an atypical human liver alcohol dehydrogenase, however, which is reported¹⁴ to produce a faster drop in blood alcohol concentration due to increased ethanol oxidation. *D. melanogaster* inhabits a wide range of environments and flies have been found in habitats with temperatures near 40° C. Thus the variation found in *Drosophila* alcohol dehydrogenase may be relevant to natural populations.

I thank Geoffrey Hudson and Roger Ison for assistance.

Long Chain Fatty Acid Formation: Key Step in Myelination studied in Mutant Mice

MYELIN is the most stable membrane known and the fact that it contains ten times as much long chain sphingolipid as any other known membrane structure has led to the suggestion that the long chain fatty acids (>18 carbon atoms) in these sphingolipids are concerned in the stability of myelin^{1,2}. The finding^{3,4} of a myelin deficient mouse mutant whose galactolipids and sphingomyelin lack long chain fatty acids led us to investigate whether the elaboration of long chain sphingolipid molecules is a key step in myelin formation. The comparison of histological and biochemical events related to myelination in normal and myelin deficient mutant mice supports the hypothesis that in the events leading to adult myelin, the appearance of fatty acids with 24 carbon atoms follows the appearance of cerebroside and sulphatides in myelin.

The two myelin deficient mutant mice, "Quaking" and "Jimpy"⁴, manifest symptoms at the time of myelin formation, around the tenth day after birth. Although they have the same apparent phenotype, characterized by an abnormal gait, tremor and seizures, they have a different genotype; the Quaking mutation is autosomal and recessive; the Jimpy mutation is sex linked, X linked, implying that genes located on at least two chromosomes are involved in myelin metabolism and control. Unlike Quaking mice, Jimpy mutants do not reach adulthood; their disease is more severe and histological and biochemical data relate this to an earlier stage corresponding to myelination. Glial cells normally multiply after birth and reach maximum density just before the onset of myelination. Second, they extend processes along the axonal fibres, so forming a myelinating glia constituted of oligodendrocytes whose function is analogous to that of the Schwann cell in the peripheral nervous system. In the Jimpy mouse there is a lack of myelinating glia⁵; by contrast, the normal types of neuroglial cells are present in the Quaking mouse⁶, but the glial cells may be qualitatively deficient, for vacuoles and inclusions have been demonstrated inside their cytoplasm⁷.

The biochemistry of myelination is still rather obscure. Galactolipids are the only lipids characteristic of brain white matter⁸. Experiments with radioactive isotopes have shown that cerebroside and sulphatides are synthesized at birth⁹⁻¹¹; galactolipids, especially cerebroside, are only detectable in a significant amount at the onset of myelination¹² and possibly are of key importance in this process⁹: the other lipid components of myelin have been shown to occur in other membranes and are already present in large quantities at birth. In the Jimpy mouse, the cerebroside and sulphatide content is negligible¹³, which correlates with a very early impairment in the process of myelin formation. By contrast, cerebroside and sulphatides are formed in the Quaking mouse although they are deficient in long chain fatty acids with 24 carbon atoms.

Myelin was isolated from the Quaking mouse to study whether myelin was only deficient in quantity or whether its composition was abnormal in relation to a maturation process involving the appearance of long chain fatty acids in sphingolipid molecules. We compared Quaking adult myelin with that of apparently normal adult litter mates using the method of Norton *et al.*¹⁴. We also isolated by the same method myelin from 12 day old apparently normal mice. The proportions of proteolipid to lipid showed little variation between young and adult stages. The values obtained for the molar ratios of phospholipids, cholesterol and galactolipids were similar to those observed by Norton *et al.*¹⁴ and Eng *et al.*¹⁵ for the rat, with a molar ratio of galactolipids to phospholipids of 0.28 at 12 days and 0.64 at 3 months. Comparison of the fatty acid pattern in 12 day old myelin lipids with that of adult brain myelin lipids confirmed the increase with age of

stearic and oleic acids¹⁶; moreover, the proportion of long chain fatty acids (with 24 carbon atoms) was 10–11 per cent of the total fatty acids in adult normal myelin (Table 1). By contrast, the fatty acids of 12 day old myelin included only small amounts of long chain fatty acids (Table 1), although cerebrosides and sulphatides were already present. In the Quaking mouse, the lipid composition and protein content were closely related to the values observed in the early days of myelination, there being a great deficiency in long chain fatty acids (Table 1).

Table 1. FATTY ACID COMPOSITION (PER CENT) OF BRAIN MYELIN LIPIDS

	Adult normal	12 day old normal	"Quaking" adult
C ₁₄ :0*	0.30	1.40	0.30
C ₁₆ :0	12.64	27.43	24.82
C ₁₈ :0 + C ₁₈ :1	45.87	35.15	43.50
C ₂₀ :0 (?)	5.85	11.32	8.43
C ₂₀ :1	7.13	—	0.50
C ₂₂ :0	5.98	12.79	10.50
C ₂₂ :1	2.01	0.31	0.86
C ₂₄ :0	4.50	2.14	1.08
C ₂₄ :1	7.09	2.04	0.66
C ₂₄ :2	3.69	1.27	0.78

* Gas chromatography of fatty acid methyl esters of brain myelin lipids on 10 per cent SE 52 column. Temperature, 225°C. Flow rate, 25 ml. nitrogen/min. The results are the average of three analyses. The normal mice correspond to apparently normal homozygote and heterozygote littermates of Quaking mice.

* Fatty acids are identified by the number of carbon atoms and number of double bonds (for example C₁₈:0 = stearic acid); h indicates the presence of a 2-hydroxy-group.

It seems therefore that in the normal maturation process leading to adult myelin, the appearance of fatty acids with 24 carbon atoms follows the appearance of cerebrosides and sulphatides. A deficiency in long chain sphingolipid molecules as observed in the Quaking mouse may lead either to cessation of myelination or to the formation of unstable myelin² and may explain the loose configuration of early myelin¹⁷. The key step (blocked in the Quaking mutation) may be the formation of these long chain fatty acids or their association with a cerebroside precursor through the action of chain length specific enzymes. Myelin membrane proteins may also be concerned: they are known in other membranes to determine the association of lipids containing specific fatty acids¹⁸.

Genetic Effects of ¹³¹I in Mice

We have already studied¹ the genetic effects of phosphorus-32 and warned against its indiscriminate use before or during the child bearing age. We report here an investigation of the genetic effects of ¹³¹I. ¹³¹I is a beta and gamma emitter with a half life of 8.04 days and an energy spectrum of 0.188 \bar{E}_B MeV. It is widely used for diagnostic and therapeutic purposes in doses ranging from 16 to 200 μ Ci and 50 to 700 μ Ci respectively in human medicine.

A survey of the medical history of ¹³¹I indicates that a dose of 563 μ Ci used to treat thyroid carcinoma induces sterility². In another report³, ¹³¹I injected into the pregnant woman was found to be concentrated in the 18 week old foetus and its immature Graafian follicles. Bengtsson *et al.*⁴ have also reported that ¹³¹I is concentrated in the Graafian fluid.

Male mice of inbred strain C3H/He aged 10–12 weeks were given an intraperitoneal injection of ¹³¹I in the form of sodium iodide in 0.5 ml. of isotonic saline solution in doses of 0.2, 0.5 and 0.7 μ Ci. It should be noted that intraperitoneal injection is not the same as the oral or intravenous routes used medically. 24 h after injection, each treated male was mated with three untreated females of the same age. Vaginal plugs were examined every morning and females which had copulated were replaced by fresh females. The mated females were dissected on the fifteenth day of gestation and the number of live and dead embryos (including deciduomata) were recorded. Control observations were made on females mated to untreated males.

Table 1 gives the results of mating during the first four weeks, and they show that injection of ¹³¹I had a demonstrable effect on the intrauterine deaths.

The observations clearly indicate mutagenic effects of ¹³¹I in mice. Fig. 1 shows graphically the effect during the different periods of mating (1–4 weeks).

The peak period for all doses seems to be the second and third weeks. The sperm screened during these periods would probably have been in the spermatid stage at the time of injection⁵. The high sensitivity of spermatids agrees with the observations of others using X-rays⁶ and ⁹⁰Sr (ref. 5). The significantly high incidence of intrauterine deaths during the first and the fourth weeks suggests that ¹³¹I could also cause chromosomal breaks in spermatozoa and spermatocytes. The results of this investigation point to the possible hazards of any indiscriminate use of radioiodine in human medicine.

The mechanism of mutagenic action needs further exploration.

Table 1. RESULTS OF MATINGS (1–4 WEEKS) OF MALES INJECTED WITH ¹³¹I (DATA FOR FERTILE MATINGS ONLY)

Dose	♂♂ treated	Weeks	Females dissected	Total No. of implants	Dead	Per cent dead	Dead per female
Control	50	1	98	615	22	3.58	0.22
		2	52	411	21	4.86	0.40
		3	67	483	11	2.27	0.16
		4	59	481	22	4.57	0.37
Total		1–4	276	1,990	76	3.81	0.27
0.2 μ Ci	100	1	57	435	49	11.2	0.85
		2	109	698	101	14.46	0.92
		3	112	743	62	8.3	0.55
		4	121	963	49	5.08	0.40
Total		1–4	399	2,839	261	9.19	0.65
0.5 μ Ci	100	1	60	498	44	8.83	0.73
		2	133	1,032	150	14.54	1.12
		3	104	843	104	12.33	1.00
		4	113	892	106	11.86	0.9
Total		1–4	410	3,265	404	12.37	0.98
0.7 μ Ci	100	1	87	909	132	14.5	1.5
		2	76	653	105	16.0	1.3
		3	105	960	128	13.3	1.2
		4	96	796	60	7.53	0.62
Total		1–4	364	3,318	425	12.8	1.16

P value for the comparison between control and 0.2 μ Ci is $0.02 \leq P \leq 0.05$ and for the comparison between 0.5 μ Ci and 0.7 μ Ci it is $0.50 \leq P \leq 0.70$ whereas for all other comparisons $P \leq 0.001$. (The conclusions are based on 1–4 week totals only.)

Fig. 1. The percentage of intrauterine deaths when matings took place 1-4 weeks after the males were injected with ^{131}I . ○, Control; ●, 0.2 μCi ; ▲, 0.5 μCi ; ■, 0.7 μCi .

Antineoplastic Components of Marine Animals

REFERENCES to the biological properties of marine organisms date back to antiquity¹. For example, hieroglyphics on the tomb of the Egyptian Pharaoh Ti (approximately 2700 BC) described the poisonous puffer fish *Tetraodon stellatus*. Perhaps the earliest recorded use of a marine organism in primitive medical practice occurred when the Roman, Plinius Secundus (AD 29-79), recommended that the sting unit of the stingray be ground up and used for treatment of toothache and in obstetrics. The first modern pharmacological and chemical studies of a substance from a marine animal probably involved tetrodotoxin from the poisonous puffer fish (for leading references see refs. 2 and 3). In recent years, extracts from certain sponges and coelenterates have been shown to have antibiotic properties⁴⁻⁶. There have also been indications that marine invertebrates produce various other potentially medically useful components⁷⁻¹¹. Most important from the standpoint of cancer chemotherapy have been observations that starfish meal¹²⁻¹⁴ and the peanut worm *Bonellia fuliginosa*^{15,16} and that partially purified material from certain sea cucumbers [Echinodermata] have antitumour activity against sarcoma-180 and Krebs-2 ascites tumour^{10,17-19}. Also certain clam¹⁸ (Mollusca) extracts and material from oysters have antitumour properties⁹⁻¹¹.

In 1968 we reported²⁰ evidence for antineoplastic agents in terrestrial arthropods. During an analogous investigation of marine animals we have evaluated components from many marine invertebrates and vertebrates from a broad geographic area (Atlantic and

Pacific coasts of North and South America and the coasts of Asia). We assessed antineoplastic activity using the Walker 256 carcinoma (intramuscular) and both a lymphoid (L-1210) and lymphocytic leukaemia (PS) as developed at the National Cancer Institute.

We wish to report that at present a few representative species have given very encouraging results. Two marine animals from the Gulf of Mexico provide a general illustration. An aqueous 2-propanol extract of the bryozoan *Nugula nerita* in several doses led to 168-200 per cent life extension (PS system). Similarly an ethanol extract of *Molgula occidentalis* (Chordata/Tunicata) at 50 mg/kg gave 177 per cent life extension using the PS leukaemia. (To obtain the extract the marine animal was pretreated by extraction with ligroin and aqueous 2-propanol. Accordingly, the ethanol extract represents a partial concentration of active component(s).) In each case the material was given intraperitoneally (in carboxymethyl cellulose) on the day of transplantation of tumour into BDF₁ mice and continued for each of 10 days. Active components are now being isolated from these specimens and others, including (Bryozoa) *Amathia convoluta*, *Bugula nerita*, *Thalamaporella gothica floridana*; (Coelenterata) *Anthopleura xanthogrammica*, *Renilla mulleri*, *Tealis coriacea*; (Echinodermata) *Astropecten scoparius*, *Luidia clathrata*, *Lytechinus variegatus*, *Mellita quinqueperforata*, *Pisaster ochraceus*; (Mollusca) *Cristaria plicata spatiosa*, *Gryphus stearnsi*, *Haliotis ovina*, *Macrocallista nimbosa*, *Turbo (marmarostoma) stenogyris*; (Arthropoda) *Matuta lunaris*; (Chordata/Tunicata) *Clavelina picta*, *Molgula occidentalis*, *Styelis plicata*; (Chordata/Pisces) *Porichthys porossissimus*. One of these, the vertebrate *Clavelina picta*, has resulted in a life extension of 200 per cent (at 400 mg/kg using the PS method).

We were not surprised to confirm the antineoplastic activity of extracts of marine invertebrates, but to discover antineoplastic components among the marine vertebrates represents a stimulating new development. There are more than a million species of marine invertebrates and more than 25,000 known species of fishes, and so our results suggest that marine animals will be a particularly fruitful and interesting source of potentially useful antineoplastic agents.

Conversion of Palmitate to Respiratory Carbon Dioxide by Foetal Tissue of Man and Monkey

ALTERATION in the amount of fat deposition in the foetus is clinically well documented for anencephalic, diabetic and low-birth weight infants¹⁻³ and indicates that the rates of synthesis and degradation of foetal lipids, like those of the adult, are influenced by environmental and hormonal factors. It also suggests that the human foetus anabolizes or catabolizes lipids at different rates in response to pathological conditions of gestation. Observations in man and rabbit have shown that the foetus anabolizes lipids essentially from carbohydrate precursors and does not apparently catabolize lipids^{4,5}. If this is true, fatty acids would not be catabolized to respiratory carbon dioxide (CO₂) by foetal tissue in normal conditions. The assumption is open to question because slices of human foetal liver incubated with labelled fat have been shown to metabolize this substrate to respiratory carbon dioxide⁷.

We attempted to show that the foetus is able to degrade fatty acids *in vitro*. Slices of placenta, brain, liver and lung from human and monkey foetuses obtained at various periods of gestation by interruption of normal gestation were studied. Each incubating vessel contained 2.2 mmoles of purified palmitate-1-¹⁴C (specific activity 15 μ Ci/mmol obtained from New England Nuclear Corporation) dissolved in a total volume of 3 ml. of albumin-Krebs-Ringer phosphate pH 7.4 with 10 mmoles of added glucose⁶. The purity of radioactive palmitate, determined by gas chromatography, was found to be 98 per cent.

Brain, liver and lungs were incubated for 1 h in an atmosphere of 95 per cent O₂ and 5 per cent CO₂. The CO₂ was trapped in alkali, placed in the centre well of the incubation flask (0.2 ml. of a carbon dioxide-free 5 per cent solution of sodium hydroxide). At the end of the incubation this solution was washed into centrifuge tubes containing water, the CO₂ was precipitated as BaCO₃ and transferred quantitatively to scintillation vials containing a mixture of toluene with 4 per cent 'Cab-o-Sil' and 4 g/l. of BBOT (Packard Instruments)⁷. The radioactivity was determined in a scintillation counter (counting efficiency: 82 per cent).

Because of the dilution of the radioactive palmitate by the amount of unlabelled fatty acids in the incubating system⁸, the incorporation of palmitate to CO₂ was expected to be low. As control, slices of placental tissue were incubated in a nitrogen atmosphere or at 0°C with labelled palmitate. No significant radioactivity could be detected in the trapped carbon dioxide. Each sample was counted long enough to obtain a standard deviation of ± 3 per cent (95 per cent confidence limits). All data were submitted to the Student's *t* test or analysis of the variance.

Fig. 1 and Table 1 show that palmitate is oxidized to CO₂ by each foetal, newborn, and adult tissue studied. The degradation of palmitate to CO₂ by human and monkey placental tissue increases as a function of time ($P < 0.01$ at 60 min). Liver and lung tissue of both man and monkey catabolizes palmitate to CO₂ more actively than brain tissue ($P < 0.01$). Though the problem of

Fig. 1. Respiratory ¹⁴CO₂ production from palmitate-1-¹⁴C by placental tissue. The results are the mean \pm s.e. of four 13-14 week (○), and six term (●) human placentas. The results of two 60-90 day (△) and term (▲) monkey placentas are also shown. All determinations were carried out in duplicate.

dilution in tissue by endogenous palmitate is difficult to resolve, the findings suggest that palmitate is either selectively retained as brain lipid, diluted into a large cellular free fatty acid pool, or does not cross into brain cells as readily as in other tissue. The first hypothesis is the most probable because the net synthesis of lipids from palmitate in the human and monkey foetal brain tissue is as fast as that of liver, lung, or placenta⁸. In monkey tissue and in the human placenta, the rate of production of respiratory CO₂ from palmitate does not vary with development. Adult and newborn lung tissue, however, catabolizes palmitate to CO₂ more actively than foetal lung tissue. This could be the result of an increased rate of palmitate catabolism by lung tissue after delivery. At birth this tissue assumes its respiratory function, so it is to be expected that the overall metabolism of lung lipids will increase^{9,10}, resulting in increased CO₂ production from glucose or fatty acid precursors.

The oxidation of palmitate to CO₂ by these tissues demonstrates the presence in the foetus of the β , α or ω oxidative enzymes which catabolize the stepwise cleavage of two carbon units from the long chain fatty acyl-CoA beginning from the carbonyl end¹¹. It sheds some doubt on the consensus of opinion that the foetus only anabolizes lipids⁴, but suggests rather than metabolic pathways are available to oxidize fatty acids in foetal tissue, as they are in skeletal muscle, liver, heart and kidney of the adult animal¹².

Failure of 5 α -Dihydrotestosterone to initiate Sexual Behaviour in the Castrated Male Rat

In most mammalian species the principal steroid product of the testes is testosterone, 17 α -hydroxyandrost-4-en-3-one. In addition to being one of the most potent naturally occurring androgens it has been considered to be the active form of the hormone at target tissue level. Recent reports suggest, however, that a metabolite of testosterone, 17 α -hydroxy-5-androstan-3-one (5 α -dihydrotestosterone (5 α -DHT)), may be the active form of the hormone^{1,2}. Several target organs (prostate, seminal vesicle and penis) rapidly convert testosterone to 5 α -DHT (refs. 1 and 2). This conversion occurs before the attachment of the hormone to the receptors³ and seems to be essential for subsequent protein synthesis. Additional evidence for this function of 5 α -DHT comes from studies on patients with testicular feminization; tissue biopsies from the genital organs of such patients cannot convert testosterone to 5KDNT (ref. 4). Testosterone can also activate both male and female sexual behaviour and is more potent than oestrogens in inducing libido in women⁵. Recently the enzyme system needed to convert testosterone to 5 α -DHT has been demonstrated in the hypothalamus of the rat and dog^{6,7}, which suggests that 5 α -DHT may also be the active form of testosterone in inducing sexual behaviour. In the ovariectomized female rabbit, however, 5 α -DHT is devoid of any oestrus-inducing properties at doses from 2–20 mg per day⁸. 5 α -DHT cannot be converted to oestrogenic metabolites *in vivo*⁹, which suggests that the aromatization of androgens may be of significance in the activation of sexual behaviour. This preliminary report concerns the failure of 5-DHT to initiate sexual behaviour in the castrated male rat.

Three groups (six animals each) of sexually inexperienced mature male Wistar/Sprague-Dawley rats were housed in community cages with 14 h light and 10 h dark per day. Food and water were provided *ad libitum*. Animals in group 1 served as intact controls. Six weeks before testing began, all the rats in groups 2 and 3 were bilaterally castrated. Testing was carried out once daily during the second half of the normal light cycle (1400 to

1700 h) in large open-fronted cages. In each test the male was placed in the cage 2–3 min before the female and was removed from the cage after the female. Observations were made either for 15 min or until the occurrence of the first intromission following ejaculation. If no activity took place in the first 7.5 min the test female was replaced. Ovariectomized females were brought into oestrus with a single subcutaneous injection of 100 μ g oestradiol benzoate 48 h before testing. After fourteen daily tests, rats in group 2 received daily subcutaneous injections of 100 μ g testosterone propionate (TP) for 8 days and animals in group 3 received 125 μ g 5 α -dihydrotestosterone propionate (5 α -DHTP) daily for 8 days. Testing continued for a further 9 days. The rats were autopsied after the final test and the body weights and seminal vesicle and prostate weights were recorded.

During the first week of testing none of the animals showed any sexual activity (Table 1). A high level of performance was reached by the intact controls and TP-treated animals by the final week, whereas only one rat treated with 5 α -DHTP responded; this consisted of a single mount in one test (Table 1). During the first week of treatment the performance of the TP males was lower than that of the intact group, but by the final week the activity of the two groups did not differ significantly, except for ejaculation latency which was significantly longer in the TP treated males ($P < 0.05$). The behavioural responses show that the period of treatment with TP was sufficient and suggests that the failure of 5 α -DHTP to activate sexual behaviour was probably not the consequence of the length of the injection period. The autopsy weights (Table 2) confirm that 5 α -DHTP is almost as potent as TP and that complete restoration of the sex accessory glands is not necessary for the re-initiation of sexual behaviour.

Table 1. COMPARISON OF THE NUMBER OF RATS RESPONDING AND THE NUMBER OF POSITIVE TESTS OBTAINED IN INTACT CONTROL AND CASTRATED ANDROGEN-TREATED RATS

Period	Group No.	No. of rats	No. of tests	No. of rats responding	No. of positive tests
Control (weeks 1 and 2)	1	6	14	3	9

3	125 μ g 5-DHTP	455.7 \pm 38.3	113.68* \pm 11.5	44.03 \pm 5.8

* Significantly different from controls and from each other at 1 per cent.

† Significantly different from controls at 1 per cent.

Testosterone can be aromatized *in vivo* to give rise to oestrogenic metabolites¹⁰, and this has been suggested as a possible mechanism by which testosterone could induce sexual behaviour⁵. The failure of 5 α -DHTP to induce sexual behaviour in castrated male rats and ovariectomized female rabbits may therefore be because this compound cannot be aromatized⁹.

If this is the case, the aromatization of testosterone may be an important step in the activation of sexual behaviour in both the male and female. In support of this, androst-sterone—another androgen which cannot be metabolized to oestrogenic compounds—does not activate sexual behaviour in the ovariectomized rabbit (unpublished observations of C. B. and N. Vidal). Clearly, additional compounds will have to be tested before this concept can be finally accepted.

The 5-dihydrotestosterone propionate used in this study was kindly supplied by Dr P. Crabbe, Syntex de Mexico.

Aglycogeusia: the Inability to recognize Sweetness and its Possible Molecular Basis

Two patients have been found who could not recognize the taste of any sweet substances. This has afforded us apparently the first opportunity to study this phenomenon; we have called it aglycogeusia.

The patients, both male, were aged 18 and 19, and had congenital idiopathic hypoparathyroidism. This diagnosis was made soon after birth in each patient following spontaneous seizure activity. Lower than normal serum concentrations of calcium were found in each and responded to treatment with exogenous calcium and/or vitamin D with the elimination of seizure activity. No specific aetiology of their hypoparathyroidism was established.

Detection and recognition thresholds for each of four taste qualities were determined in these patients by a slight modification of a forced choice, three stimulus drop technique previously described in detail^{1,2}. Sodium chloride was used for the salty taste, sucrose for sweet, hydrochloric acid for sour and urea for the bitter taste. In addition, their subjective taste responses to drops of saturated solutions of D-fructose, D-glucose, D-galactose, D-xylose, sucrose and phenylthiocarbamide (PTC) were determined. Responses to 1 per cent, 50 per cent and saturated solutions of sodium cyclamate were also obtained. These responses were determined on at least five occasions for each substance.

Detection thresholds (the lowest concentration of solute distinguishable from water) for each of the four taste qualities tested were within normal limits in each patient. Recognition thresholds (the lowest concentration of solute recognized appropriately) for three qualities, salt, sour and bitter, were also within normal limits. Neither patient, however, could usually recognize dilute and saturated solutions of sucrose as sweet. Oral administrations of other dilute and saturated sugar solutions were also not usually recognized as sweet. The subjective responses of the patients to these various solutions were similar and are shown in Table 1. Fructose and sucrose usually elicited a sour response, while glucose, galactose and 1 per cent sodium cyclamate usually elicited a bitter

response. D-Xylose, the only pentose in the group, usually elicited a salty response.

Taste acuity was studied in both patients over a period of two years, and on no occasion did they give a consistently sweet response to any sugar. Neither withdrawal of their replacement therapy, which lowered their serum calcium concentration, nor its reinstitution, which returned serum calcium concentration to normal, was associated with any change in their aglycogeusia. These observations suggest that the aglycogeusia in these patients is not associated with their abnormality of calcium metabolism, but rather is a genetic concomitant of their hypoparathyroidism, a disease which is often familial and may be transmitted as a recessive autosomal genetic defect³. Normal taste responsiveness to sugars has been observed in patients who exhibit hypocalcaemia after surgically produced hypoparathyroidism and in others with idiopathic hypoparathyroidism which occurs after the first several years of life. These normal taste responses which occur in presumably non-genetic abnormalities of the parathyroid glands contrast with the aglycogeusia found associated with a presumed genetic abnormality of the parathyroids.

Sensory, metabolic and other abnormalities have been associated with congenital idiopathic hypoparathyroidism (such as adrenal cortical insufficiency⁴, deafness (unpublished observation of R. I. H.) and moniliasis⁵). Both patients had bilateral sensorineural hearing losses, and one had severe cutaneous moniliasis. Aglycogeusia is probably another of the sensory defects found in these patients, and present, presumably, from birth.

Aglycogeusia in these patients is not associated with the inability to recognize PTC as bitter, for both recognized this substance as bitter even in dilute solutions. In addition, they recognized urea and sodium cyclamate as bitter. The distribution of aglycogeusia in the population at large is not known, for its presence has not previously been reported. It seems, however, to be a rare phenomenon, because in more than 2,000 patients with various acute and chronic illnesses in whom taste thresholds have been measured, it has appeared only in these two. Indeed, taste thresholds measured in one further patient with congenital idiopathic hypoparathyroidism were completely within normal limits.

Recently, a molecular theory of the taste of sweetness was proposed which related hydrogen bonding and specific molecular spatial parameters to specific degrees of sweetness^{6,7}. In this theory sweetness was related to the interaction between a sweet tastant and a receptor site, both of which possessed a "hard-acid" function AH and a "hard-base" function B (ref. 8). The sweet taste presumably occurs after the formation of a simultaneous intermolecular hydrogen bond between these complementary moieties. The optimum distance range between AH and B on both receptor and tastant in order for this interaction to occur is hypothesized to be about 3 Å.

Kubota and Kubo⁸ have recently postulated that one of the chemical features common to compounds which have a bitter taste, presuming an AH, B type receptor site, is that the presumed AH, B distance parameter is 1.5 Å and, as a result, a strong intramolecular hydrogen-bond is formed in the bitter compound.

Given these hypotheses, a possible explanation for the responses of our patients to galactose and glucose may be

Table 1. SUBJECTIVE TASTE RESPONSES TO VARIOUS SUBSTANCES IN TWO PATIENTS WITH AGLYCOGEUSIA

Substance*	Taste response
D-fructose	sour
D-glucose	bitter
D-galactose	bitter
D-xylose	salty
sucrose	sour
sodium cyclamate, 1 per cent	bitter
sodium cyclamate, 50 per cent	bitter
sodium cyclamate	bitter
phenylthiocarbamide	bitter

* Saturated solutions presented, except 1 per cent and 50 per cent sodium cyclamate.

based on stereochemical phenomena which exist in the intrinsic structure of the sweet tastants, the sugars themselves. Galactose and glucose have a stereostructure which makes possible the formation of intramolecular hydrogen bonds. For galactose in the favoured chair conformation in the axial hydroxyl group at C4 is sterically disposed to hydrogen bond to the ring oxygen atom and this may relate to its bitter taste to an aglycogeusia. Glucose as the β -D-anomer, with its hydroxyl constituents all in the unfavoured axial disposition, has its hydroxy-methylene group sterically disposed to hydrogen bond with the anomeric hydroxyl group, and this may account for its bitter taste. The only difference between xylose and glucose is the absence of the hydroxy-methylene group on the fifth carbon atom, and the patients called this taste salty. In patients with aglycogeusia, fructose elicited a sour response, possibly because of the relatively high acidic character of its anomeric hydroxyl group.

Our data suggest that taste specificity may be explained by a two-site receptor in which the molecular distance between the sites is of critical importance. The molecular abnormality in patients with aglycogeusia may be an abnormality in the intersite distance parameter.

Specificity of Internal Signals in producing Satiety for Taste Stimuli

A GUSTATIVE sweet stimulus gives rise to a pleasant perception in fasting human subjects. The same stimulus will seem unpleasant after ingestion of a hypertonic glucose load^{1,2}. What is the nature of the internal signal responsible for this shift in perception from pleasant to unpleasant? McCleary has shown a relationship between the osmolality of the administered fluids and food intake and has suggested³ that satiety may be a result of extracellular dehydration. Other workers have also supported the importance of osmotic factors in alimentary behaviour and the close relationship between food and water intake⁴⁻⁷. We therefore decided to look at the influence of osmotic pressure in the affective transformation of taste perception in the human after ingestion of glucose and saline.

Experiments were conducted during the morning on twenty healthy, naïve, non-obese, fasted subjects of both sexes (no difference in the response was observed between sexes), ranging from 18 to 26 years old. They were offered two series of gustatory stimuli: NaCl at concentrations of 10, 5, 2.5, 1.25, 0.5 and 0.25 g/100 ml. in a volume of 25 ml. The sample was retained in the mouth for 15 s, was then expectorated and the subject gave a

quantitative response ranging from -2 to +2 describing the pleasantness or the unpleasantness of the taste. The scale was infinite, but the following grades were assigned: -2 very unpleasant, -1 unpleasant, 0 neutral, +1 pleasant, +2 very pleasant. After each stimulus the subject rinsed his mouth thoroughly with tap water. When all the test samples had been offered at random with double blind precautions and the responses had been recorded, the subjects ingested 200 ml. of a solution containing either glucose or sodium chloride. Ten subjects drank 50 g of glucose in solution while the other ten subjects received 15 g NaCl in solution through gastric tubing. All subjects therefore received an equal volume of a very hypertonic fluid. One hour later the same samples were offered, using the same method.

Fig. 1 shows that sweet perception, pleasant to fasted subjects, turned unpleasant at all concentrations after glucose ingestion (χ^2 test $P < 0.10$, Kruskal-Wallis test $P < 0.01$), but was not significantly changed after gastric

Fig. 1. Affective responses to varying concentrations of sweetness. ●—●, Control (N=20); △---△, 1 h after glucose load (N=10); □---□, 1 h after NaCl load (N=10).

Fig. 2. Affective responses to varying concentrations of saline. ●—●, Control (N=20); △---△, 1 h after glucose load (N=10); □---□, 1 h after NaCl load (N=10).

hypertonic NaCl. There was a significant decrease only for the most hypertonic sucrose gustative stimulus (χ^2 test $0.2 P < 0.5$), but to a much smaller extent than after glucose ingestion. Fig. 2 shows the average responses after NaCl gustative stimuli on fasted subjects; the taste was unpleasant at all concentrations. Ingestion of the amount of hypertonic glucose needed to render unpleasant sweet stimuli did not significantly change the affective responses to NaCl, but these responses were significantly lowered, that is, slightly more unpleasant, after intragastric NaCl (χ^2 test $P < 0.01$) for all concentrations offered.

These results show that the shift from pleasant to unpleasant sweet perception for sucrose in man is probably not related to osmotic internal signals but seems to be more specific and related to the chemical nature of the ingested solute. They also show that internal signals are involved in affecting perception.

These results confirm the previous finding in rats which showed the importance of the gustative inputs in producing satiety^{5,8}. Arguments have been presented against⁸⁻¹⁰ or in favour of^{5,11,12} a specific satiety for sucrose and NaCl. Our results favour the second hypothesis.

Decline of Tissue Noradrenaline under the Influence of a Mitotic Inhibitor

MATERIALS are transported down axons by two processes: a slow process of bulk axoplasmic flow moving at 1–6 mm/day and a fast transport process which is thought to be mediated by neurotubules and moves at 10^2 – 10^3 mm/day¹. Drugs such as colchicine, which inhibit mitosis by interfering with the formation of the mitotic spindle, interact also with neurotubules, indicating that the neurotubule and the mitotic spindle may be homologous structures². Colchicine inhibits both fast³ and slow⁴ intra-axonal protein transport, suggesting that neurotubules may be associated with both processes. Granules containing noradrenaline are transported down sympathetic nerves by a fast process⁵ which is inhibited by local application of colchicine⁶. Vinblastine, a mitotic inhibitor used in the treatment of certain cancers, affects formation of neurotubules⁷, and we have injected vinblastine intravenously into rats in an attempt to interfere with the intra-axonal transport of noradrenaline in sympathetic nerves generally.

Figs. 1 and 2 show the effects of a single dose of vinblastine on the noradrenaline content of heart, brain, spleen and vas deferens of male Sprague-Dawley rats (200–250 g). Noradrenaline was measured by a modification of the phenylethanolamine-N-methyltransferase

Fig. 1. The effect of a single dose of vinblastine (3 mg/kg, intravenously) on the noradrenaline content of rat heart (○) and vas deferens (●) expressed as a percentage of control values. Noradrenaline levels in control animals were: heart, $0.76 \pm 0.03 \mu\text{g/g}$; vas deferens, $11.26 \pm 0.60 \mu\text{g/g}$. Each point the mean (\pm s.e.) of not fewer than four and not more than eleven animals.

Fig. 2. The effect of a single dose of vinblastine (3 mg/kg, intravenously) on the noradrenaline content of rat brain stem (○) and spleen (●) expressed as a percentage of control values. Noradrenaline levels in control animals were: brain stem, $0.55 \pm 0.02 \mu\text{g/g}$; spleen, $1.32 \pm 0.10 \mu\text{g/whole spleen}$. Each point the mean (\pm s.e.) of not fewer than four and not more than eleven animals.

method⁸. Vinblastine reduced the noradrenaline contents of the spleen, heart and vas deferens to respectively 10, 20 and 50 per cent of control values, but had no effect on brain noradrenaline levels. There was a delay before the effect of vinblastine was seen: approximately 30 h in the heart and vas deferens and more than 12 h in the spleen. The rate of fall of noradrenaline levels in the vas deferens was much slower than that in the heart or spleen, possibly a reflexion of the slower turnover rate of noradrenaline in the former. In each case noradrenaline levels started to recover at about 10 days after administration of vinblastine; by 21 days cardiac noradrenaline levels had risen to 40 per cent of control values. Treated rats are being examined over longer time periods to determine whether complete recovery occurs.

The difference between the basal levels in heart and vas deferens (Fig. 1) suggests that because, unlike the heart, the vas deferens contains cell bodies as well as nerve endings, vinblastine could have blocked axonal transport so that the decline of noradrenaline levels could represent a decline of nerve-ending noradrenaline while the residual noradrenaline in the vas deferens could represent noradrenaline remaining in the cell bodies and axons. The rate of depletion of cardiac noradrenaline after vinblastine is, however, more rapid than that which follows inhibition of noradrenaline synthesis⁹ and so interference with axonal transport of noradrenaline cannot be the sole cause of the decline of noradrenaline levels. Possibly vinblastine interferes with the transport of some nutrient which is essential for noradrenaline storage at the nerve-ending and the delay period represents the time taken for existing stores of this nutrient to become exhausted. Despite its profound effect on sympathetic nerves, vinblastine did not cause any obvious impairment of function in motor nerves of treated rats, although vincristine, a related alkaloid, has been reported to cause degenerative changes in motor and sensory nerves in both rat¹⁰ and man¹¹.

Tetrahydrocannabinol Isomers and Homologues: Contrasted Effects of Smoking

Two isomers of tetrahydrocannabinol (THC) are found in natural marijuana preparations. 99 per cent is in the form of $\Delta^1(9)$ -THC, which is very active when taken orally or smoked^{1,2}. A Δ^3 -THC homologue, synhexyl (pyrahexyl), has been found to be about one-third as active as Δ^1 -THC, given orally to the same individuals³. The study I report here compared measured doses of Δ^1 -THC, the Δ^3 -homologue (synhexyl), and Δ^3 -THC smoked by the same individuals, using a placebo and blind controls.

Ordinary commercial cigarettes were treated to give sets of four containing: (a) Δ^1 -THC, 12 mg, obtained from extraction of natural marijuana. The method for extraction has been described elsewhere³; the extract includes undetermined amounts of cannabinol and cannabidiol, as well as the specific amounts of Δ^1 -THC. (b) Synhexyl, 15 mg. (c) Δ^3 -THC, 15 mg. Both synhexyl and Δ^3 -THC were synthetic and measured gravimetrically. The synhexyl was provided by Dr R. Gwinn of Abbott Laboratories, N. Chicago, Illinois, and the Δ^3 -THC by Professor R. Mechoulam, School of Pharmacy, Hebrew University of Jerusalem. (d) Placebo, containing marijuana extract

from which all cannabinoids had been removed by prior extraction. Cigarettes were treated by injecting alcoholic extracts of each material throughout their length, with the exception of a small butt area, and evaporating to dryness under nitrogen. Cigarettes were stored until use in sealed tubes kept in a refrigerator. The tubes were identified only by code number, the order of treated cigarettes having been randomized.

Six experienced cigarette smokers were chosen as subjects on the basis of their habituation to nicotine and their ability to inhale fully and deeply. Each cigarette was smoked almost completely, using an unfiltered holder so that only a half-inch butt was left. Each of the four trials was separated by an interval of at least 48 h. The assignment of cigarettes was not known to the smoker or his monitor. Smoking involved deep inhalation and retention of the smoke for at least several seconds after each intake, the whole process being completed in 3–4 min.

The monitor obtained subjective reports of the effects of each smoking trial by frequent questioning during the entire span of action of the smoke. Pulse rate (three records) and the appearance of the conjunctiva were noted before each trial and at intervals of 10 min during trials.

Each of the six subjects had unmistakable effects from smoking the cigarettes containing 12 mg of Δ^1 -THC. Symptoms usually became apparent after three deep inhalations, and always by the time the cigarette was finished. Initial symptoms of numbness and tingling of the extremities, light-headedness, "floating" feelings and loss of concentration were followed by palpitation, sweating, tremulousness and weakness which lasted for varying times. Increasing mental impairment—described as difficulty in paying attention, difficulty in expression, mental confusion, loss of time sense, or a feeling of euphoria—was evident within 30 min. Some subjects complained of a dry mouth or burning feeling in the throat. Two subjects became quite sleepy and a third slept for about 2 h. Five of the six felt mentally clear between 60 and 90 min after smoking, but the one who slept was impaired for 4 h. Five of the six subjects had pulse rate increases of 10 or more beats/min, the mean increase being 20 beats. Five of the six subjects had unmistakable reddening of the conjunctiva, which appeared within minutes and tended to last as long as clinical effects were noticed.

Each of the subjects experienced definite effects from smoking cigarettes containing Δ^3 -THC, but these were less severe. Initial symptoms were light-headedness, numbness and tingling in extremities or face, fatigue and cold perspiration. Effects became evident before smoking was completed in four of the six subjects. Fatigue, drowsiness, sleepiness or a feeling of relaxation was prominent after 10 min and one subject fell asleep for 30 min. Impaired thinking and time sense distortion were not as prominent as with the Δ^1 -THC cigarettes. Subjects felt mentally clear 45 to 80 min after smoking. Only three subjects had a rise in pulse rate over 10 beats/min, the mean rise being 10 beats. Only three of the six subjects had reddened conjunctivae.

Compared with the other cigarettes, those treated with synhexyl elicited complaints of dry mouth or burning throat more often. Other symptoms were similar: light-headedness, numbness and tingling of face and extremities, drowsiness, lethargy and sleepiness, sweating and pallor, tremulousness, difficulty in thinking and speaking, mild confusion, and mild euphoria. As with the other active cigarettes, symptoms came on rapidly, but in one subject nothing more was noted than burning in the throat. The other five subjects had symptoms lasting from 45 to 150 min after smoking. Four of the subjects had increases in pulse rate greater than 10 beats/min, the average being 13 beats. Three of the six showed conjunctival injection.

The mere technique of smoking the placebo cigarettes, with deep inhalation and prolonged retention of smoke in the lungs, produced at least some symptoms in each

subject. Usually these were brief, no subject reporting any symptoms after 30 min. Early feelings of dizziness and light-headedness were the most common; one subject reported tingling of hands and nausea. Only one subject experienced more symptoms from the placebo cigarette than from the active ones, this being the subject who reported little effect with the Δ^3 -THC cigarette. Two subjects had pulse rate increases of more than 10 beats/min, the average being 8 beats. One had questionably reddened conjunctivae.

The effects of smoking Δ^1 -THC from marijuana extract were strongest and resembled those obtained from oral doses of the same extract in other experiments⁴. Onset was more rapid, and the experience briefer and more intense, when doses were smoked. Both the Δ^3 -THC isomer and its homologue, synhexyl, had activity like that of marijuana when smoked, but were considerably less potent than the Δ^1 -THC isomer. An estimate of the potency ratio might be 1:3 to 1:6. In the case of Δ^3 -THC, our results differ from those of others, who reported no effects from smoking almost twice the dose (400 μ g/kg) of the same isomer¹. Some unusual effects were noted from the placebo, but were not easily confused with those from the sizable doses of marijuana-like materials used in the present study. It is likely that the effects produced by placebo cigarettes were caused by the rather different technique for smoking marijuana, as compared with conventional, cigarettes.

Inhibition by Drugs of Smoking Behaviour in Monkeys

THERE have been several analyses of the role of nicotine in smoking. Johnston¹ found that heavy smokers reported a pleasurable sensation when given nicotine, whereas non-smokers reported an unpleasant effect. Lucchesi *et al.*² showed that intravenous administration of nicotine diminished the number of cigarettes smoked by heavy smokers. Jarvik *et al.*³ recently obtained a similar result with nicotine taken orally. If, as these studies suggest, nicotine is an incentive in smoking, then drugs which block the action(s) of nicotine should influence smoking.

Because of the relative ease of controlling environmental contingencies, an animal paradigm of smoking behaviour has been developed in this laboratory⁴⁻⁶. In an attempt to modify smoking behaviour, various drugs have been given to four mature rhesus monkeys trained to puff cigarette smoke.

Puffing behaviour was initially instilled by making the monkeys suck on a tube in order to drink. The mouthpiece of a cigarette smoking apparatus⁵ was then substituted for the water tube. The smoking apparatus allowed a monkey to smoke lit cigarettes by automatically lighting each cigarette, spacing the cigarettes over time and sensing changes in pressure as the monkey puffed. When the monkeys had learned to puff, they were so trained that they had to puff but were allowed to choose between smoke and air⁶. This procedure was developed to reduce

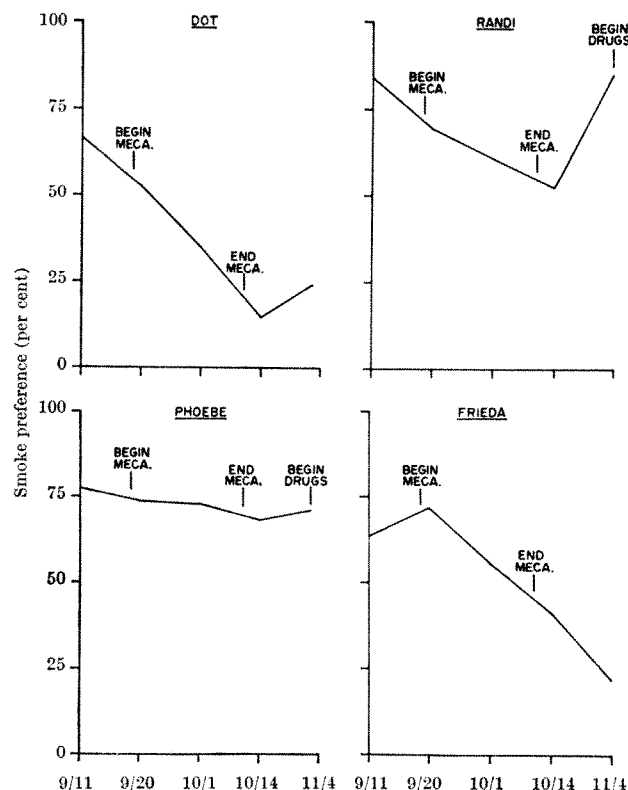

Fig. 1. Changes in smoke preference on non-drug days induced by mecamlamine.

the large variability from subject to subject inherent in free puffing.

A smoking apparatus was attached to a 'Plexiglas' panel covering a 14 inch square opening in the door of each monkey's home cage. Two tubes, one delivering cigarette smoke and a "dummy" tube with access only to air, were also mounted on the panel. A water solenoid was mounted between the smoke and air tubes. A puff on either the smoke or air tubes preset the solenoid and would release a small amount of water when the monkey touched the solenoid spout. A light mounted above the solenoid signalled the availability of water. A fixed ratio (FR) contingency was added, so that a monkey could be required to puff a specific number of times to obtain water.

The monkeys received all their water during a daily 4 h puffing session. Thirty cigarettes were loaded into the smoking apparatus each morning and the test was started at 1030 h. A new cigarette was automatically lit every 7.5 min. The positions of the smoke and air tubes were interchanged each morning so that side preferences would not develop. Initially, water could be won with a single puff on either the smoke or air tube. The number of puffs for a reward of water was then increased to five, ten, twenty and finally to thirty. The FR 30 schedule was then maintained. Puffs were recorded on Sodeco counters and on an Esterline Angus recorder.

All four monkeys preferred smoke to air; that is, although they could get water by puffing on either the smoke or the air tubes, they reliably made more puffs on the smoke tube than on the air tube. When puffing rates on the FR 30 schedule stabilized, drug administration began.

The first drug was mecamlamine which is known⁷ to block both the peripheral and central effects of nicotine. Mecamlamine, in doses ranging from 0.4 to 3.2 mg/kg, was given intramuscularly 15 min before the beginning of a puffing session. Each dose was repeated two to five times, with at least 3 days between successive injections.

The results obtained from mecamlamine administration are shown in Table 1. The data on days immediately

Fig. 2. Typical Esterline Angus puffing records.

preceding injections were used as control data in paired *t* tests. For each monkey, a dose of mecamlamine was found which reversed the smoke-air preference while producing a small decrease in the overall puffing rate.

We had not expected that mecamlamine would make smoke less desirable than air. If mecamlamine blocks the incentive effect of nicotine, then one might reason that smoke and air should be equally rewarding or that smoking should increase in order to get more nicotine and overcome the block. The reversal suggests that nicotine is the rewarding component in cigarette smoke and that smoke without nicotine is aversive. Mecamlamine, by blocking nicotine, may leave only the aversiveness of smoke itself.

It took approximately a month with two injections a week to complete the course of mecamlamine administration summarized in Table 1. During this time a gradual and consistent change in the smoke-air preferences under non-drug conditions was noted. The smoke preferences of the monkeys decreased and, after the last injection of mecamlamine, two of the monkeys still preferred air to smoke. Fig. 1 shows this progression for each of the monkeys, two of which recovered their preference for smoke. The other two monkeys, whose initial preferences were lower than those of the first two, did not recover within a 1 month period of observation. This long term after-effect of mecamlamine administration could be ascribed to negative conditioning; that is, repeated experience with smoke as an aversive stimulus precluded the rewarding effect of nicotine.

Table 1. CHANGES IN SMOKE PREFERENCE INDUCED BY MECAMLAMINE IN MONKEYS

	0.4	114*	24.2*	1,143*	14.8*
Mecamlamine	1.6	3,844	14.1*	4,553	15.2*

* Significantly less than control at $P < 0.05$.

When the smoking preferences of the two recovered monkeys stabilized, the drug experiment was continued with them. Doses of pentobarbital, hexamethonium, scopolamine and D-amphetamine were given, in that order. One final dose of mecamlamine was also given. The results obtained from this series of injections are shown in Table 2. Pentobarbital, a barbiturate anaesthetic, decreased the overall puffing rate but did not change the smoke-air preferences. Hexamethonium, a nicotinic-blocker in the periphery which does not readily enter the brain⁷, reversed the smoke-air preference with large doses while decreasing the overall puffing rate. Scopolamine, a cholinergic blocking agent, and D-amphetamine, an adrenergic agonist, also reversed the smoke-air preferences and overall puffing rates were greatly decreased. Mecamlamine, again, reversed the smoke-air preferences with a small decrease in overall puffing rates.

The pentobarbital results indicate that a preference reversal is not just an artefact caused by decreased overall puffing. The hexamethonium results suggest that a peripheral action of nicotine may be part of the smoking incentive. Alternatively, in view of the much lesser potency of hexamethonium as compared with mecaml-

amine, perhaps a small amount of hexamethonium entered the brain.

A comparison of the patterns of puffing with the various drugs suggests that the scopolamine and D-amphetamine results may have been an artefact of decreased overall puffing. Fig. 2 shows sample patterns of smoke and air puffing under each of the drugs. Puffs are distributed fairly evenly in non-drug conditions and with mecamlamine, hexamethonium and pentobarbital. In contrast, puffing with scopolamine and D-amphetamine was completely suppressed for at least the first hour of the test session. Puffing on the air tube with these two drugs may have been a rebound after-effect caused by increased thirst when the drugs had been physiologically eliminated. To confirm this interpretation, we ran a deprivation test. A daily puffing period without drugs was started 2 h later than usual. Both monkeys had reversed smoke-air preferences at the beginning of the test sessions. Increased thirst may thus make smoke more aversive.

The results of this experiment must be qualified because of their questionable correspondence to human smoking. The forced and restricted nature of the monkeys' puffing certainly bears little resemblance to the free and intermittent smoking by humans. The ultimate importance of the present results will depend on their therapeutic significance. If, as these data suggest, nicotinic-blocking drugs will inhibit smoking by humans, then the animal paradigm will have been a most useful one.

This work was supported by grants from the US National Institute of Mental Health and the American Cancer Society, and a postdoctoral fellowship from the US National Institutes of Health.

Belief in the Supernatural among Harvard and West African University Students

JAHODA¹ has assessed the effect of university education on traditional supernatural beliefs held by many students at the University of Ghana, and concluded that there was no evidence that education, "including scientific training, had any discernible impact on the magico-mythical beliefs". He therefore suggests that if such beliefs impede the growth of science in developing countries, methods other than general education must be used to diminish them. The growth of a superstitious sub-culture now apparent in the United States, including increased popular interest in horoscopes, and our desire to understand better the African studies, led us to attempt a similar investigation on undergraduates at Harvard University.

Two hundred male students at Kirkland House of Harvard College answered, on a scale from 0 to 20 chosen to match Jahoda's, a questionnaire containing nine questions. With instructions explaining that 0 indicated "total unqualified disbelief", 10 indicated "neither belief nor disbelief", and 20 indicated "total unqualified belief",

they were asked whether they believed in astrology, extra-sensory perception, flying saucers, and the power of prayer. Two questions, whether science could ever predict "human actions" and "all physical occurrences", were set aside because of ambiguous phrasing. We also asked the students whether they ever crossed their fingers to bring themselves luck, "knocked on wood", or "walked under ladders", with 0 indicating "never" and 20 indicating "always". We believe that the selection effect is negligible (because essentially all those having dinner on a certain night in January 1969 were polled), and that the students were answering honestly. The smallest number of students who answered each of the questions, and their distribution by year and field of study, are shown in Table 1. Because not all respondents answered quite every question, and because the table headings omit the three freshman, five staff members, and five who answered "other" to major field, the column totals are not exactly the weighted averages of the subcategories.

Table 1. MINIMUM NUMBER OF STUDENTS ANSWERING EACH QUESTION

	Second year	Third year	Fourth year	All years
Humanities	10	14	4	33
Social sciences	33	28	23	90
Natural sciences	13	6	9	32
Biological sciences	11	5	6	24
All fields	71	58	43	194

The average belief in astrology was only 2.5 on our scale of 20, extra-sensory perception was as much as 11.9, flying saucers was 8.5, and the power of prayer was 8.0. Thus many students at Harvard do not reject the supernatural, although they do not accept such fixed systems of belief as astrology. Table 2 shows the distribution of averages by year in university and by major field of concentration. Even for astrology, for which 161 students indicated disbelief by giving assessments of 5 or less, sixteen students gave neutral scores of 10, and nine students, almost 5 per cent, assessed their belief at 15 or better. Only 35 per cent were nearly certain that flying saucers do not exist, with 30 per cent neutral and 20 per cent strongly believing.

Table 2. AVERAGE BELIEF ON A SCALE FROM 0 TO 20

	Second year	Third year	Fourth year	All years
(a) Do you believe in astrology, that the stars affect our actions on Earth?				
Humanities	3.5	4.0	3.8	4.5
Social sciences	2.8	0.9	2.7	2.0
Natural sciences	0.2	2.0	2.0	1.2
Biological sciences	1.6	0.0	3.0	1.5
All fields	2.3	2.1	2.6	2.5
(b) Do you believe in extra-sensory perception (ESP)?				
Humanities	13.5	12.0	13.7	13.0
Social sciences	13.8	11.1	12.4	12.8
Natural sciences	9.6	11.0	7.5	8.9
Biological sciences	12.1	8.0	10.5	10.9
All fields	12.6	11.0	11.2	11.9
(c) Do you believe in flying saucers?				
Humanities	10.0	7.2	8.0	9.0
Social sciences	12.0	0.6	8.9	9.3
Natural sciences	6.4	9.0	4.9	6.1
Biological sciences	6.9	7.0	8.8	7.7
All fields	9.6	6.9	8.0	8.5
(d) Do you believe in the power of prayer?				
Humanities	5.7	7.0	12.5	7.8
Social sciences	9.7	7.8	7.7	8.7
Natural sciences	6.2	4.0	6.9	6.0
Biological sciences	11.5	3.4	9.2	9.5
All fields	8.4	6.7	8.0	8.0

Students of the natural sciences believed markedly less than their fellows in astrology, extra-sensory perception and flying saucers. Assuming a standard error of about 2, there are no clear differences between students of the humanities and social sciences. Natural scientists also seem less believing in the power of prayer, although the fluctuations in these data are higher and hence the conclusion is less significant. It is interesting that students of the biological sciences tended to have higher belief scores than their natural science peers. There is no obvious correlation with number of years of university education.

The students replied that they almost never crossed their fingers to bring themselves luck or "knocked on wood", with assessments of 2.7 and 3.5, respectively. The symmetrical distribution of answers to the question about walking under ladders, with an average score of 10.3, may reflect an ambiguity in the wording of the question, although it could also reflect a cultural habit.

Thus a sizable fraction of the well educated students under study do not reject beliefs in supernatural explanations, though the scientists tend to be somewhat more sceptical. The overall level of superstition is sometimes substantial among Harvard students. At the University of Ghana, where Jahoda¹ found "mean belief scores" between 5 and 8 out of 20, his data showed that the science students did not differ from the overall sample, as they tended to at Harvard. Of course, we asked different specific questions and evaluated replies in a different manner, so our study cannot be used to provide an American baseline for his work.

We thank the master and senior tutor of Kirkland House, Harvard College, for their cooperation, and Professor Owen Gingerich and the Smithsonian Astrophysical Observatory for their assistance with computing facilities.

"Put Away"—For How Long?

MORRIS¹ has stated that "In subnormality hospitals . . . most patients, once admitted, will never leave." In the past this was true, but the present trend is for subnormal individuals to remain at home, adequately supported by appropriate services, for as long as possible. Moreover, it has been shown that 10 per cent or less² of populations of subnormality hospitals require "detailed specialist day to day diagnosis, care and treatment"³. 80 per cent of severely subnormal children now remain at home⁴. One of the services which can extend the time for which families can tolerate a mentally handicapped dependant at home is periodic short term care in hospital. Of all admissions to mental subnormality hospitals and units in England and Wales, 48 per cent in 1964 and 60 per cent in 1966 were for informal short term care, usually for eight weeks or less⁵. We present here a short account of a study aimed at discovering whether the same factors determine short term and long term care for children and fulfil the same needs.

In this hospital during 1964-66 it was possible to offer either short term or permanent care almost equally readily; of 373 admissions, 58 per cent were for short term care. Subsequently, there has been almost no option for long term care, irrespective of the need. After exclusions (such as multiple admissions), 285 records were studied, and the results analysed by computer.

Of the 164 short term care children, only 9 per cent remained in longer than eight weeks; of the long term admissions, 5 per cent remained in for less than eight weeks, and 89 per cent remained over a year. Although more boys than girls were admitted, as has been observed elsewhere^{6,7} the same proportion of each sex came in both for short or long term care. Penrose⁸ thought that probably society was less able to tolerate inadequate role performance among males; fortunately it seems that, if so, the in-

tolerance is as likely to be temporary as permanent. Similarly, there was no significant difference in the age on admission of the children who came in for long term or short term admissions; 46 per cent of the short term and 41 per cent of the long term care patients were between 1 and 4 years, and 21 per cent of each type of care were between 4 and 7 years old.

110 of the children, 43 per cent of those formally psychologically assessed, were profoundly retarded (IQ below 20) and a further 127 (49 per cent) were severely or moderately retarded (IQ 20-51), but as the age on admission increased, so did the proportion who were profoundly retarded: 62 per cent of 37 children admitted under the age of 1 year, 67 per cent of 116 admitted between 1 and 4 years; 89 per cent of 54 between 4 and 7 years; and 85 per cent between 7 and 10 and 10 and 13 years were profoundly retarded according to tests.

When the reasons for which hospital care had been requested were considered, significantly fewer of the short term care children were reported to be illegitimate or to present difficulties of management in the home, or to have serious physical disabilities (excluding spastic cerebral palsy or epilepsy, which occurred in approximately one third of both groups). An assessment of the parents' health indicated that maternal physical illness was associated with 42 per cent of the short term admissions, but with only 24 per cent of long term admissions.

Physically, approximately three quarters of both groups were in good general condition, requiring no active medical treatment. Of those measured⁹, four fifths of the children were below the average for their age in height, and three quarters were below average in weight, in both groups. The most commonly seen physical defect was squint, which in varying severity was noted in one quarter of both groups, although the general population incidence has been estimated as 1-2 per cent¹⁰. Emotionally, in both groups less than a tenth of the children were overactive, destructive, aggressive, self-mutilating or excessively attention-seeking.

We conclude that at the present time over half the patients admitted to subnormality hospitals will leave again within a few weeks. Objectively, there is little to distinguish those who leave from those who do not. It therefore seems that community care, backed where necessary by short term residential care, will increasingly become a superior alternative to long term residential care for severely mentally handicapped children, and few indeed will "never leave".

We thank Mr Eisenberg, Mr Duckor and Miss Meredith for their help; the Institute of Computer Science for the use of the Atlas Computer of the University of London; and the South West Metropolitan Regional Hospital Board for their research grant which enabled us to secure the help of Mrs Edlin.

Book Reviews

BELOW THE SEA FLOOR

Initial Reports of the Deep Sea Drilling Project

Vol. 1: Orange, Texas to Hoboken, NJ, August–September 1968. Pp. xx + 672. \$10.25. Vol. 2: Hoboken to Dakar, Senegal, October–November 1968. Pp. xx + 490. \$8.25. (Prepared for the National Science Foundation, National Ocean Sediment Coring Program by the University of California, Scripps Institution of Oceanography.) (US Government Printing Office: Washington DC, February 1970.)

On August 12, 1968, the drilling vessel *Glomar Challenger* began boring its first hole in the Gulf of Mexico. Compared with the aims of the Mohole project, which was finally abandoned two years earlier, the aims of the Deep Sea Drilling Project were modest: the acquisition of information pertaining to the history of the ocean basins.

These two splendidly produced and illustrated volumes cover the first two legs of the project. On the first leg various holes were drilled in the Gulf of Mexico and the eastern North Atlantic; the second group of drillings took place in the North Atlantic on a line between New York and Dakar. The volumes contain excellent descriptions of the holes drilled and the rocks found in them; but are written mostly in technical language, with the detailed results on which any conclusions are based. They will provide a superb foundation for future work on the drilling cores, but neither they nor the shorter cruise reports of later legs convey any of the excitement which the project has generated. Nor do they (and indeed nor should they!) make any attempt to discuss the wider implications of the results of these studies.

Before this project began little was known about the sediments and volcanic rocks below the sea floor. The soft surface sediments had been cored to a depth of 10 m in many places, and loose fragments of basalt and other basic and ultrabasic rocks had been dredged. The age and composition of the huge wedges of sediment which extend from the continental slopes beneath the abyssal plains were, however, quite unknown. Before samples of these rocks had been obtained, many geologists claimed that the few rocks now exposed on the continent had been deposited in the deep ocean basins. As soon as cores of these rocks were obtained, however, they were found to be remarkably similar to the rocks which form some major mountain belts.

Perhaps the youth of the ocean basins and their economic importance are the two most surprising and important results of the deep drilling programme. When drilling began in 1968 the theory of sea floor spreading had just become accepted by most geophysicists, and large parts of the world's oceans had been dated by using the characteristic shape of magnetic anomalies observed at the sea surface. There was, however, rather little evidence to support the reversal time scale used for this purpose. The spreading rates obtained from the magnetic anomalies also required almost all the ocean floor to have been produced in the 200 m.y. since the Jurassic, or in the last twentieth of the geological record. Therefore if these results were correct the ocean floor had to be very much younger than the continents, where rocks of 3,000 m.y. have been found in several regions. The deep drilling results have supported all these suggestions in the most remarkable way. Particularly impressive is the comparison

of the dates obtained from microfossils just above the basalt in the South Atlantic with the dates from the magnetic anomalies¹. The agreement between the two is remarkable, and removes any lingering doubts about sea floor spreading and plate tectonics.

The other major result of this programme is the discovery of deposits of salt, sulphur, oil and copper beneath the deep ocean. A salt dome in the Gulf of Mexico was drilled during the first leg, and the rocks obtained contained a considerable quantity of oil and sulphur. The first of these volumes contains a description of the exhaustive experiments which were carried out to show that the rocks are identical in almost all respects to the cap rock of certain Gulf Coast salt domes. Seismic reflection records in the Gulf of Mexico show that there are a great many of these structures beneath the sea floor, many of which are likely to have trapped oil. Salt domes have also been found in deep water beyond the continental edge in the North Atlantic, and these also should have trapped oil. How the salt is formed is far from clear; Ewing *et al.* in volume one remark: "The regional problem which probably will be most earnestly debated is whether this salt was deposited in its present deep water environment, or on a crust which was once much shallower". Both proposals have major objections. Though there is not yet any method of exploiting the oil deposits trapped by the salt, there is little doubt that the intriguing technical problems can be overcome and the oil extracted. The quantities involved will probably equal or exceed those on land. The other major economic find is native copper, found on leg 11 in the deep ocean off Cape Hatteras. This discovery is less surprising than the salt domes because the oceanic crust consists of layered basic intrusive complexes, and most continental economic deposits of copper, chromium and nickel are associated with such complexes, some of which may be fragments of uplifted oceanic crust. The present drilling ship can only drill through a few metres of basalt, and therefore cannot hope to reach most of these ores. Perhaps it will soon be possible to revive the Mohole project under a different name and justify it on economic grounds alone. Let us hope that the exploitation of these enormously valuable deposits will not be permitted until it can be done without polluting the oceans with waste products and escaped oil.

WEDDELL'S VOYAGE SOUTH

A Voyage towards the South Pole performed in the Years 1822–24

Containing an Examination of the Antarctic Sea (1827). By James Weddell. Pp. x + 324. (David and Charles Reprints: Newton Abbot, June 1970. First published in 1825.) 75s.

On February 20, 1823, the *Jane of Leith*, a 60 ton sealer under the command of Captain James Weddell, a retired master in the Royal Navy, reached latitude 74° 15' S, in longitude 34° 16' a point in that great bight of the Antarctic continent which Weddell named for George IV, but which was soon to become better known as the Weddell Sea. He was only 945 miles distant from the South Pole and virtually open water lay in all directions. This remarkable southing beat Cook's previous record of 71° 10' S and was itself not to be surpassed in this sector until 1912 when the German, Wilhelm Filchner, attained 77° 44' S in the *Deutschland*. It marked an epoch in the history of Antarctic exploration by pointing to one of the principal routes to the far south, but one that in most seasons is so ice infested that few vessels can penetrate it. Dumont d'Urville, Wilkes and Clark Ross

all subsequently failed in their efforts to surpass Weddell's achievement. Filchner's Deutschland and Bruce's Scotia narrowly escaped disaster and Shackleton's Endurance drifted for ten months before finally succumbing to the almighty pressure of its pack. This was Weddell's second voyage to the Antarctic and it was, by no means, the first to harvest fur seals in the waters south of Cape Horn. Only a few years previously, in 1819, another British sealer, William Smith, had revealed the riches of the South Shetland Islands. But these early sealers were a secretive lot, not given to keeping logs let alone writing books.

Weddell's narrative, first published in 1825, the second edition (1827) of which David and Charles have now reprinted at a tenth of its current auction room value, is of singular interest. It combines one of the very few published accounts of the Antarctic sealing industry at this period with numerous observations on the natural history of the region by an amateur with all the makings of an objective scientist. The text is illustrated with careful charts of the track of the Jane and the Beaufoy (Captain Brisbane), which accompanied her; of Tierra del Fuego, the South Shetland Islands, and of the South Orkney Islands, visited only days after their discovery by George Powell. In addition to the textual descriptions of fauna, flora and the nature of the ice there are appended sections which include "Observations on the Navigation round Cape Horn", a discourse on the use of chronometer and tables of computed longitude. Illustrated is one of the five truly Antarctic seals discovered by Weddell and named for him *Leptonychotes weddelli*. In this enlarged edition are added "Observations on the Probability of Reaching the South Pole", in which Weddell argues the open polar sea theory, and, in conclusion, "Second Voyage of the Beaufoy to Tierra del Fuego", a very brief account of Brisbane's visit to the Fuegian Indies in 1825. The reprint is prefaced, aptly enough, by Sir Vivian Fuchs, director of the British Antarctic Survey, among whose responsibilities is the maintenance of Britain's Weddell Sea scientific station, Halley Bay, and who himself narrowly escaped Shackleton's fate when the expedition ship Theron was temporarily beset in these waters while attempting to establish an advance party for the Commonwealth Trans-Antarctic Expedition in December 1955.

H. G. R. KING

ANTARCTIC ICE

International Symposium on Antarctic Glaciological Exploration

(ISAGE), Hanover, New Hampshire, USA, September 3-7, 1968. Edited by A. J. Gow, C. Keeler, C. C. Langway and W. F. Weeks. (Publication No. 86 of the International Association of Scientific Hydrology and the Scientific Committee on Antarctic Research.) Pp. xvi + 541. (c/o SCAR, Scott Polar Research Institute: Cambridge, 1970.) 84s; \$10; B.f.50.

THIS collection of papers is an excellent representative selection of recent Antarctic glaciological research. It is generally up to date for the year of the symposium, 1968. The articles are grouped under thirteen sections and include presentations of technique, theory, data and general reviews. The emphasis is on the historical and regional aspects of mass ice balance, glacial meteorology, and "deep sounding", which includes deep core drilling, deep probing, and radio echo and seismic exploration. The increasingly important field of glacio-chemistry is represented in two sections devoted to studies of accumulation and particles. Analyses of the dynamics and thermodynamics of ice sheets are presented in two rather short sections. There are also sections devoted to fringe regions of the ice sheet, ice shelves and sea ice. The latter two topics are singled out, along with the ice-rock interface, as promising frontiers of Antarctic glaciology

in the frank and witty presidential address by A. P. Crary.

The great impact of the relatively new techniques of deep core drilling and radio echo sounding on Antarctic glaciology is very well shown in the "deep sounding" sections and many new applications of these tools are suggested. Even mishaps can sometimes be put to good use, as in J. Weertman's estimate of minimum water layer thickness from upwelling into a borehole. The eclectic nature of glaciology and the proliferation of sub-disciplines is impressed upon the reader, as suggested by the enumeration of subjects earlier.

Among the highlights of the symposium are the results of the studies of ice structure in the cores from the deep drill hole at Byrd Station by A. J. Gow, the detection of reflecting horizons within the ice by aerial radio echo sounding over a wide sector of Antarctica by G. de Q. Robin, *et al.*, movement studies of the Ross Ice Shelf by C. Swithinbank, and review articles on mass budget of the ice sheet as a whole by P. A. Shumsky and J. Hollin.

While most of the articles are complete, a few are only abstracts. The figures and tables are consistently pointed and readable; bibliographical completeness varies with the author. This volume will be of great value to glaciologists, but there is also much of interest to geophysicists, meteorologists, oceanographers, Pleistocene geologists and students of the polar regions in general.

GILBERT DEWART

PULSATIONS ABOVE THE EARTH

Geomagnetic Micropulsations

By J. A. Jacobs. (Physics and Chemistry in Space, Vol. 1.) Pp. viii + 179. (Springer-Verlag: Berlin and New York, 1970.) 36 DM; \$9.90.

ANYBODY who has ever had the need to browse through issues of the old *Journal of Terrestrial Magnetism and Atmospheric Electricity* published during the 1920s and 1930s will know that they were devoted almost exclusively to magnetic and electrical effects above the Earth's surface. Indeed, the few per cent of the Earth's surface field produced externally attracted attention in inverse proportion to its strength. This state of affairs has changed radically over the past twenty years; but, palaeomagnetism notwithstanding, it is still true that more papers are published on the external than the internal field. While investigations into the magnetic field produced inside the Earth have received much of the scientific limelight in recent years, studies of the external field have been going from strength to strength, notably since the advent of the artificial satellite.

Professor Jacobs's new book is concerned with one small aspect of the external magnetic field—geomagnetic micropulsations, those fluctuations of the field whose amplitudes range from a fraction of a gamma to, occasionally, as much as a few tens of gammas, and whose periods lie between 0.1 second and 10 minutes. It is not a review of all the work that has ever been carried out in this field but rather a summary of our present state of knowledge, which means, roughly speaking, a concentration on the progress made during the past decade. A long section on the morphology of geomagnetic micropulsations is followed by a consideration of magnetohydrodynamic waves, the basis of modern theories of micropulsations. This leads naturally into the theories themselves. The final, and most interesting, chapter discusses the insight that studies of micropulsations have given us into the magnetosphere itself. As Jacobs himself points out, one of the most exciting aspects of the subject is the way that micropulsations are being used, and will be increasingly used, for remote sensing of the magnetosphere.

Geomagnetic Micropulsations would be classed as a research monograph (and a good one), which means that

it would be tough reading for a newcomer to the subject. The choice of approach is, of course, Jacobs's prerogative. Even so, I would like to have seen a somewhat longer introductory chapter discussing in greater detail the philosophy and nomenclature of the subject. Jacobs is, however, to be congratulated on sticking to cgs units throughout. It really is quite monstrous that attempts should be made to force all scientific disciplines into using a system of units which may be appropriate to some but not others. The tragedy is that, irrespective of whether or not geophysicists ultimately capitulate, modern students brought up on a strict diet of SI units will be largely cut off from geophysics' most glorious decades.

PETER J. SMITH

INTRODUCTION TO PHYSICS

General Physics

By G. J. Aitchison. Pp. viii + 522. (Chapman and Hall: London, April 1970.) 60s.

THIS book is described in the preface as intended for students doing first year university physics courses with the probability of terminating their study of the subject at that level. Before commenting on this particular use, let it first be said that this is an extremely satisfactory book about physics, with a freshness of thought and an appeal to down-to-earth and commonsense reason which makes it something that few textbooks of physics are—readable. It is therefore a little disappointing that it moves forward to what has for a decade or two been the inevitable culmination of any treatment of “general physics”—high energy nuclear physics and the strange particles. Although this section is well done, one hopes that before long the much more open-ended climax offered by cosmology will replace this restricted field in the canon.

One is tempted to speculate whether this book would not be an admirable introduction to the subject for a very large number of able people who would like to understand something about physics, but have never followed it beyond school days, at least as part of their formal education. It has the qualities of a book which can be read and thought about at the pace which suits the reader, and with a little determination to follow the author's advice and do all the examples, the exercise could hardly fail to be profitable.

As a first year textbook, it has the same excellent qualities, but for this purpose it would be necessary to shape the courses to be compatible with the aims and methods of the book. A general impression is that rather more time would be needed than is sometimes allocated to a “subsidiary” subject; moreover, any examination on the course would have equally to be related to the author's view.

Here is a book which makes physics neither remote nor mysterious, and it deserves to do well.

J. G. WILSON

CONDUCTING STATES

Amorphous and Liquid Semiconductors

Edited by Sir Nevill Mott. (Proceedings of the International Conference held at the Cavendish Laboratory, Cambridge, September 24–27, 1969.) Pp. xii + 626. (North-Holland: Amsterdam, 1970.) Hfl. 108; 252s; \$30.

THE editor and everybody concerned must be congratulated for producing this very valuable volume in record time, though a penalty is paid in many printing errors. Interest in amorphous and liquid semiconductors has grown rapidly in the past few years, but our knowledge of

them is still in its infancy, so that many of the contributions are in the nature of pioneer work.

Even if some of these substances have important technological applications, the theory is of predominant interest at this stage. It is much more complicated than for crystalline semiconductors and its principal aim is to discover the differences between regular and disordered structures in the electronic energy spectrum and in the character of the energy states, the problem of the localization of these states being in the forefront. The very clear review paper on the theory is by Morrel Cohen, who points out what may be universal features of the electronic structures of disordered systems. He discusses the model which has emerged largely through the work of Sir Nevill Mott. An isolated energy band in a disordered material is assumed to consist of extended states between two critical energies, with tails of localized states outside these energies. Tails from neighbouring bands may overlap. The transport mechanism also changes at the critical energies E_c ; for the extended states it is similar to that in crystals, but, because the carriers are almost continuously under the influence of the scattering centres, their motion is more like a Brownian motion than a wave propagation; for the localized states we have phonon assisted hopping. The mobility changes by several orders of magnitude within a range of order kT about E_c , thus it is more appropriate to speak of a mobility edge and mobility gap rather than of an energy gap.

S. F. Edwards explores, in an elegant paper, the analogy of the Mott transition with a phase change of a thermodynamical system. He establishes a relation between the density of states of the electrons in a disordered system and the thermodynamics of a flexible chain, so that the problem is reduced to counting the configurations of this chain. The result is that a phase change can indeed take place. It is not yet certain whether the conductivity drops to zero quite abruptly.

The title of the last section, “Non-ohmic Behaviour of Semiconducting Films and the Phenomenon of Switching”, brings to mind the work of S. R. Ovshinsky, and he himself is in fact co-author of five articles. In one of them, with H. Fritzsche, he discusses the conducting state in covalent alloy semiconductors which is maintained only above a certain value of the current, and the various processes that can trigger this high field breakdown. Another contribution by H. K. Henisch, E. A. Fagen and Ovshinsky discusses switching in monostable structures in terms of a double injection space charge model.

It is a pity that in a short review it is impossible to mention several other important contributions. In brief, we have here a collection of absorbing descriptions of the early exploration of a vast field.

L. PINCHERLE

TALK AT CORAL GABLES

Coral Gables Conference on Fundamental Interactions at High Energy 2

Center for Theoretical Studies, University of Miami, January 21–23, 1970. Edited by A. Perlmutter, Geoffrey J. Iverson and Ruth M. Williams. Pp. x + 369. (Gordon and Breach: London and New York, 1970.) \$22.50.

FOR several years now the University of Miami has been host to a winter conference on elementary particle physics organized by Professor B. Kursunoglu. The earlier meetings were restricted to symmetry physics and they provided valuable opportunities for discussion and exposition during the heady development of that subject in the middle sixties. Now that things are quieter on the symmetry front the scope of the conference has been widened to include a broader theoretical spectrum. The volume under review covers the second of the new style Coral Gables meetings held in January 1970.

The wider range inevitably results in a more fragmented and loosely connected series of talks. Moreover, two fields of much recent interest and activity—Veneziano dynamics and deep inelastic electron scattering—are only slightly treated in the proceedings. If an underlying thread can be discerned in the majority of the contributions it is probably a concern with the use of field theoretic methods. A most interesting and promising development here is represented by Salam's talk on the new methods being developed to discuss non-polynomial Lagrangian theories. Another talk which must have been most interesting is unfortunately not recorded in the proceedings, for Gell-Mann has not provided a script for his exploration of the breaking of scale invariance.

As with many conference proceedings, some of the most interesting items occur in the records of the discussions, which provide a questioning counterpoint to talks themselves. At best, however, this type of proceedings is necessarily somewhat ephemeral. The publishers are therefore to be congratulated on producing the volume with sufficient speed to conserve its utility. It is to be regretted, however, that they have set a price which would be more appropriate for a definitive treatise with expectations of longevity.

J. C. POLKINGHORNE

FUNDAMENTAL CONSTANTS

The Fundamental Constants and Quantum Electrodynamics

By B. N. Taylor, W. H. Parker and D. N. Langenberg. (*A Reviews of Modern Physics Monograph.*) Pp. xiii + 353. (Academic: New York and London, December 1969.) 47s.

THIS book, identical with an article published in *Reviews of Modern Physics* in 1969, provides a critical and comparative review of all the work bearing on the fundamental constants of quantum electrodynamics up to 1969. The original article was prompted in part by improved measurements for electrodynamic quantities (for example, the muon g -factor, the Lamb shift in deuterium, the hyperfine splitting in muonium, the fine structure of hydrogen), and improved theoretical calculations for such quantities. The strongest motivation for this reassessment, however, was probably that provided by the new possibility of determining e/h very accurately by measurement of the Josephson-effect frequency ($\nu = 2Ve/h$) for two weakly coupled superconductors maintained at d.c. voltage difference V . From the agreement found for e/h in measurements of ν in a wide variety of circumstances, the authors argue that any corrections to this simple formula are less (and probably much less) than $1/10^6$. Using the Josephson effect, they can obtain a value for $\alpha = e^2/hc$ without any essential use of quantum electrodynamics; with this value for α , they are then in a position to check empirically the quantum electrodynamic expressions given by theory, including the higher order corrections.

The book is very technical in its account of this subject, which is full of complex interrelationships, and the details discussed at length will be of interest primarily to the specialist on fundamental constants and experiments relevant to their determination. Their recommended set of fundamental constants will, however, be of more general interest, and the book includes an interesting chapter discussing what experimental and theoretical work is still needed to establish more reliably the fundamental constants. Section E ("Recommendations for Reporting Results") of this chapter could well be read by every research worker, for it illustrates the deficiencies of detail which critical readers find in many published papers today and which made the task of these authors unnecessarily difficult.

I am not completely clear why this book has been published. Its contents are readily available in a journal which will be found in every library likely to stock the book. The book has small pages, with stiff and shiny paper, which makes it tiring to read; the pages have wide margins so that the open book presents relatively little material to the eyes. I found the original article much easier to read; the journal format allows one to grasp the material more readily (each page has three times as much material) and to turn up some particular point more quickly. Perhaps republication in book form may give the article a wider attention than it may gain from the pages of a scientific journal.

The book is too detailed and technical to serve as a text. Nevertheless, its critical yet constructive approach is likely to give it an important influence on the future development of this subject.

R. H. DALITZ

GOLDEN RULES FOR ENGINEERS

Brittle Fracture in Steel Structures

Edited by G. M. Boyd. Pp. xiii + 122. (Butterworth: London, June 1970. Published for the Navy Department Advisory Committee on Structural Steel.) 85s.

THIS book sets out to present clearly to the practising design engineer the general problems associated with brittle fractures in fabricated steel structures and to give specific recommendations on how these problems may be minimized by choice of material and control of fabricating procedure. The views expressed represent the consensus of opinion of members of the Navy Department's Advisory Committee on Structural Steels (NDACSS), but to a large extent they coincide with those of the editor, who possesses a great wealth of experience in the field of brittle fracture. Any review must be written in the context that the book is meant to educate and aid practical engineers and managers, who have only a vague awareness that an "elusive phenomenon known as brittle fracture" may cause trouble in their fabricated structures.

Brittle fracture problems are initially set in perspective by describing examples of service failures up to 1965. A detailed risk assessment is made only for the case of ships and, here, I feel that it would have been particularly interesting to have speculated on risks which could be involved with the mammoth tankers and ore-carriers now being built. A summary is made of the lessons learned from experience, and the book then continues with a description of the characteristics of brittle failures, before going on to outline ways in which mechanical and metallurgical factors may affect fracture. The separate mechanical and metallurgical effects of "massiveness" could have been expounded more clearly, and, in otherwise very good sections on welding, mention should have been made of heat-affected zone embrittlement in higher alloy ("transformable") structural steels. Tests for notch ductility are described and a review is given of the methods currently favoured by different countries for selection of steel. German, Japanese and Russian practices are included, but little comment is made on the extent to which the procedures may be said to prevent service failures.

The experience and expertise of the editor and committee emerge in the chapters which give detailed instructions on design for welding; they tread cautiously with regard to the advisability of proof testing, and recommend procedures for the selection of steels. It is pleasing to see that a consensus of opinion can provide precise Charpy impact values for specification purposes, but the Charpy test is admittedly invalid as a prime reference. The point is made, but the dependence of specific Charpy figures on the background experience of steel type and application

cannot be overemphasized. They are not necessarily appropriate to the newer high strength structural steels, yet it is precisely with these that the design engineer will feel most at sea (for example, in submarine applications).

The book has rather an old-fashioned appearance, because it tends to be a summary of past experience. The NDAOSS should be urged to anticipate future trends and to consider now the recommendations that it may have to give in the future. One of the claims for the book is that it could serve as a text for engineering students; in this respect, it does not compare particularly well with certain other works on the subject, except that some of its information is more up to date. Its principal appeal is to the practical designer and, here, its job is done well for the "classical" applications: the designer is told to use his own judgement, but is provided with a watertight procedure for choice of material and a set of "golden rules" to assist his general design and construction. It is to be hoped that designers will so discipline themselves to follow the "golden rules" that they thereby prevent brittle fracture in their iron rods!

J. F. KNOTT

FLOW PHENOMENA

Separation of Flow

By Paul K. Chang. (International Series of Monographs in Interdisciplinary and Advanced Topics in Science and Engineering, Vol. 3.) Pp. xviii+777. (Pergamon: Oxford, London and New York, May 1970.) 300s; \$40.

THERE is no entirely satisfactory name for that class of hydrodynamic phenomena which includes eddying "dead-water" regions downstream of bridge piers, behind bullets, and aft of stalled aircraft wings. The term "separated flow" is often used, because it expresses the idea that the particles of fluid which travel along the front part of the body in question do not remain in contact until they reach its downstream extremity; instead, they "separate" from the body surface at some earlier station, causing its downstream parts to be swept by fluid moving in the opposite direction. Flow patterns of this kind are frequent in engineering; they may be provoked deliberately, as in the design of combustion chambers; or they may be a tiresome adjunct of other necessities, as when the wind flows past a hyperboloidal cooling tower.

The range of separated-flow phenomena is enormous, and the scientific literature about them is growing rapidly. Whoever seeks to write a textbook on the subject should therefore have read much, and have mastered diverse experimental and theoretical material; he must, moreover, be able to write about his subject sufficiently rapidly for his book not to be too out of date when it appears, to excite interest.

Professor Chang has certainly made a commendable attempt at this difficult task. He has incorporated the results of a very large number of papers into his book of nearly eight hundred pages; and (a rare bonus) he has listed many papers which, though relevant, he has been unable to quote. The book is well organized, and on each topic the author has striven to provide knowledge of experimental findings, of theoretical analyses and of practical consequences.

The principal defect of the book is that, because it has inevitably taken many years to write, some of the material is severely dated. For example, there now exist rather satisfactory computational procedures, embodied in standard computer programs, for predicting when two-dimensional laminar or turbulent boundary layers will separate from a solid surface. Chang does not mention these, but gives space, instead, to methods which, though they enjoyed a certain vogue ten or fifteen years ago, are now largely discredited. The author has accomplished so much, that defects of this kind are no disgrace to him;

it is nevertheless the duty of a reviewer to point them out.

The book is handsomely produced. The style of the English is not entirely free from signs that the author is writing in a language which is not his own, but it reads smoothly enough. The greatest benefit that the book brings, however, is that it is a unique compilation of information old and new, on an important technological subject; many research workers will find it a useful guide to the literature.

D. B. SPALDING

REMOTE SENSORS

Synthetic Aperture Radar Systems

Theory and Design. By Robert O. Harger. (Electrical Science Series.) Pp. xiii+240. (Academic: New York and London, January 1970.) 126s.

THE synthetic aperture radar (SAR) system is primarily used to form an image of terrain from a remote location. It is a scanning system which overcomes the physical constraints which limit the more straightforward radar systems. The along-track resolution does not depend exclusively on the narrowness of the scanning beam, but is provided by Doppler processing the received echoes. The basic idea originates in the work of Carl Wiley of the Goodyear Corporation during the early 1950s. He observed that there was a one-to-one correspondence between the along-track coordinate of a reflective object being linearly traversed by a radar beam and the instantaneous Doppler frequency shift of the signal reflected by the object. A finer along-track resolution was obtained by a frequency analysis of the reflected signals than that allowed by the along-track width of the physical beam. The SAR consists of a transmitter, receiver, processor, and associated storage device. A stable oscillator serves as a common reference source for both transmitter and receiver, that is to say, the radar is coherent. The simplest data processor is an optical processor, which, in effect, is an analog computer carrying out its calculation by physical operations which very closely copy the actual generation of the radar data from the terrain the image of which is to be recovered.

The author of this book was, until recently, a member of the Radar and Optics Laboratory of the University of Michigan, where the first successful demonstration of SAR was performed in 1953 and where, in more recent years, the optical system signal-processor has been developed. The book is based on lectures prepared for the intensive course on SAR given annually since 1966 at the university, and is written on three levels. The first two chapters discuss in a simplified and general manner the principles, important parameters, and elementary system design of SAR systems. On the second level of discussion, the next six chapters deal with the optimum design of such systems. The basic limitations and sources of error are examined in some detail. The effects of phase errors, nonlinearities, motion errors and the scattering mechanism on the systems are considered. It is shown that the "ambiguity function" of the SAR is not the same as the "classical" function for a range-Doppler radar, and, that unlike the "classical" radar, the SAR possesses an inherent suppression of range ambiguities. Finally, in the last two chapters, the influence that the effects of the error sources should have on the design of SAR systems is discussed. The requirements are far more complicated and less flexible data processing.

Throughout the author gives a very clear exposition. The language of system studies is mathematical and the reader should have considerable knowledge of the theory of radar, the basic elements of matched filtering and pulse compression, optical processing and even holography. This is a pioneer and authoritative text. Each chapter concludes with valuable comments and references, and

reflects in its presentation the excellent manner in which the lecture material must have been prepared and delivered. The imaging radar system is an interesting remote sensing technique which should find application in many branches of science and engineering, particularly those concerned with earth resource surveying. No electronic circuits appear in the book, only block and optical diagrams. The student of physical optics will find much which he recognizes, and, indeed, the author pays ample tribute to the contributions of Professor E. N. Leith to the understanding and success of SAR. This is a book to be recommended to the serious student of system design engineering and particularly to those who are engaged in current research in the field of high-resolution radar.

S. WEINTROUB

COMPLEX VARIABLES

Functions of a Complex Variable

By D. O. Tall. Vols. 1 and 2. (Library of Mathematics.) Vol. 1: Pp. 72. Vol. 2: Pp. 80. (Routledge and Kegan Paul: London; Dover: New York, July 1970.) 18s boards; 9s paper (each).

This subject is one of the pleasantest in the undergraduate course. Theorems are easy to comprehend, though not always to prove, and applications are varied and fascinating; as Littlewood has said, everybody is struck on first meeting with the calculation of definite integrals by contour integration, and to this one might perhaps add conformal mapping.

The author assumes a knowledge of complex numbers, such as may be obtained from Ledermann's book in the same series, and is therefore able to discuss straightaway the topics of differentiation, integration and Taylor series. When topological properties are involved, these are clearly stated but proofs are generally omitted; most students at this stage will be prepared to accept, for instance, Jordan's curve theorem as a reasonable assumption. Cauchy's theorem is proved by means of the Stokes formula, but a proof under less restrictive conditions is given for a triangle; the step from here to the general result is again a matter for topology.

The second volume deals with applications. There is a somewhat brief introduction to conformal mapping and harmonic functions. Then we have a good account of the calculus of residues and applications, particularly to definite integrals; here the author deals carefully with principal values. The final chapter concerns analytic continuation and Riemann surfaces. In twelve small pages, only a very cursory account can be provided, and its chief use should be to whet the reader's appetite for further study.

Exercises are kept at an elementary level, and are not so numerous as to daunt the student; solutions are supplied.

T. A. A. BROADBENT

DATA FOR TOXICOLOGISTS

Handbook of Analytical Toxicology

Edited by Irving Sunshine. Pp. xiv + 1081. (Chemical Rubber: Ohio; Blackwell (Scientific): Oxford, 1969.) 280s.

This book is claimed to be a collection of data essential to scientists engaged in the analysis of drugs, poisons, and industrial chemicals. It is compiled on similar lines to the well known *Handbook of Chemistry and Physics*, from the same publisher. Types of compounds covered include drugs (the largest group, occupying about 550 pages), pesticides, described as economic poisons (113 pages), industrial chemicals (confined to those for which American threshold limit values are available) (98 pages), and smaller sections on air pollution and water analysis.

The drugs selected are those considered to be of greatest

interest to toxicologists, and inorganic compounds are excluded. Much useful data are given on toxicity, metabolism and excretion, isolation procedures and identification. Sections are included on micro melting point determinations and microcrystal tests. Ultraviolet absorption data are given for many drugs and spectra are reproduced for 290 compounds. Infrared spectra, with tables to enable many pharmaceuticals and pesticides to be identified through the well known Sadtler collection, are also provided. Large sections are devoted to chromatographic data (paper, thin layer and gas), giving R_F values or retention times in many systems, and details of detection reagents. Physical methods of analysis are discussed, including infrared, fluorescence and atomic absorption spectrometry, microdiffusion analysis, and chromatography.

A criticism might be that information on a particular subject, such as ultraviolet spectroscopy or chromatography, is divided among several sections in different parts of the book. This is, however, probably inevitable when so much material on different groups of compounds is collected in one volume, and in practice it is not difficult to find the required data.

Like other well known CRC publications this book is very thorough and detailed in its information. The tables are well supplied with references which greatly increases their usefulness. Many references as recent as 1968 are included. There is a comprehensive index.

The information provided is so vast that the book can hardly fail to be useful to anybody working in the field of drugs or toxicology. The book is strongly bound and well presented, which is to be expected in view of its high cost. Further editions are promised to bring the contents up to date in a field which is inevitably changing rapidly.

A. R. MATTOCKS

TOXIN TREATISE

Microbial Toxins

A Comprehensive Treatise. Edited by Samuel J. Ajl, Solomon Kadis and Thomas C. Montie. Vol. 1: Bacterial Protein Toxins. Pp. xxii + 517. (Academic: New York and London, April 1970.) 215s.

If workers on bacterial toxins have been able to complain, with justice, that there has been no book on their subject since a slim volume in 1951 and very patchy coverage by review articles, they can do so no longer. This is the first volume of a set of six which will deal with the bacterial protein toxins in three volumes, the endotoxins in two, and the algal and fungal toxins in the final one. The names of the authors of some projected chapters are a sufficient guarantee that their subjects will be dealt with adequately.

This volume provides a general survey of the protein toxins and has an admirable introductory chapter by van Heyningen, the author of the 1951 book. Then follow a chapter on nomenclature by Bonventre and two excellent chapters by Raynaud and Alouf on the kinetics of toxin formation and release, and on methods of purification and the properties of the purified toxins, followed by an equally good one on cytolytic toxins by Bernheimer. Both Bonventre and Raynaud and Alouf discuss the classification of toxins and come up with quite different answers to what is a thorny, but not fundamentally important, problem. Indeed, the freedom which the editors have allowed their authors has produced even more duplication than is usual in multi-author works and has also led to some lacunae. Thus, the discussion by Bullen of enterotoxaemia in sheep and gas gangrene in man, produced by different *Clostridium welchii* strains, makes an important point about the difficulty of determining the role of toxins in the pathology of some diseases, but is the only chapter on pathology in the book, although there is an excellent summary of recent work on toxin

pharmacology by Rašková and Mašek. One hopes pathology will be adequately discussed in later chapters on individual toxins. This is not likely to be true of immunology, the chapter on which is confined to practical methods of producing antibodies, with no discussion of the recent interesting work on the different types of immunoglobulin produced or on cellular immunity.

In spite of a few shortcomings, this volume is essential reading for workers in the field. Later volumes should be equally essential, but the total cost of £60 or £70 is likely to deter most of us from buying them all.

D. E. DOLBY

SEAWEED SYMPOSIUM

Proceedings of the Sixth International Seaweed Symposium

Held in Santiago de Compostela, September 9-13, 1968. Edited by Ramon Margalef. Pp. xxiii + 782. (Subsecretaria de la Marina Mercante, Direccion General de Pesca Maritima: Madrid, 1970.) \$25.

THIS well produced volume is almost twice the size of the proceedings of the fifth symposium and contains forty-two papers in the biological, twenty-five in the chemical and fifteen in the applied section. The majority are written in English, a few in French or Spanish. The papers are arranged in alphabetical order of authors in each section instead of a grouping by subject—the three sections presumably of the symposium, but these need not have been kept separate in the publication. The majority of papers deal with Phaeophyta or Rhodophyta, but two papers on *Scenedesmus*, one on *Skeletonema* and one on Quaternary diatoms have crept in.

Twenty years ago many papers on seaweeds were concerned with zonation on the shore, but although problems still exist in this field very few papers in this symposium deal directly with this topic. Several papers deal with light requirements, photosynthesis and/or growth of subtidal algae, for example, of *Macrocystis*, of a mixed community growing down to 130 m in the Mediterranean, another in the Canary Islands and another general account of the factors involved in coastal and clear oceanic water. Two interesting papers deal with mitotic rhythms and photoperiodic control of spore production in *Bangia* and *Porphyra*. In the latter, the strict control of life history from filamentous *Conchocelis* stage to thalloid phase is reiterated and the extensive vegetative propagation of the thalloid phase is also noted. In this paper there is a timely warning of the dangers of assuming that life histories determined under laboratory conditions are identical to those in the field. In another paper, however, the value of cultural life history studies in characterizing *Chaetomorpha* species is stressed. Two new taxa of *Porphyra* are recorded although here more cultural work seems desirable. Several papers fill gaps in our knowledge of algal distribution. The Laminariales figure again in interesting papers on *Eisenia*, *Sacchorhiza* and *Laminaria digitata*. Two papers feature transplant experiments and, from one, preliminary results show that the polymorphic *Chondrus crispus* retains its morphology under different ecological conditions. Few Rhodophytes have been artificially cultured through their life cycles and one paper is devoted to a careful study of several genera and will prove compulsory reading for anybody contemplating such research—the necessity to lower the nitrogen and phosphorus contents of the media is an interesting finding.

The papers in the chemical section are, as expected, largely concerned with the unusual polysaccharides synthesized by brown and red algae, while one paper provides evidence that the brown algae possess respiratory pathways similar to those of other plants. Papers in previous symposia have reported the seasonal changes in organic constituents in brown algae and this is now

amplified by a study of the tocopherols in these algae.

Commercial applications of marine algae are not well known to most scientists and the final section of this volume makes interesting reading and may stimulate other workers to study the pharmacological, manurial and preservative uses of seaweeds.

To summarize, this is an excellent book containing a wealth of interesting articles ranging over almost all aspects of seaweed research and illustrating the steady progress of the subject.

F. E. ROUND

NEW JOURNAL FOR ALGOLOGISTS

Algological Studies

Managing Editor O. Lhotský. No. 1. (Czechoslovak Academy of Sciences, Institute of Microbiology, Laboratory of Algology: Třeboň, 1970. Distributed outside Czechoslovakia by E. Schweizerbart'sche Verlagsbuchhandlung: Stuttgart.) DM 36.

THE Laboratory of Algology at Třeboň is well known for its studies on freshwater algae, especially the physiology and taxonomy of microscopic species and the problems involved in their mass cultivation. The laboratory has now begun publication of a new journal, *Algological Studies*, with an editor and editorial board drawn from the staff at Třeboň and an advisory council of internationally known phycologists.

The journal is primarily intended to serve the publication needs of the Třeboň laboratory, and the first number consists of papers describing work by resident and visiting phycologists. F. Hindák of the Institute of Botany at Bratislava contributes a taxonomic study of the family Ankistrodesmaceae (Chlorophyceae), especially the genera *Pseudococcomyxa*, *Chlorobion*, *Closteriopsis*, *Keratococcus* and *Monoraphidium*. Czech phycologists have a reputation for dealing successfully with these difficult chlorococcalean families and this useful paper maintains the tradition; numerous taxa are clearly described, including three new species and three new varieties, and a key to the genera is included. Next, J. Růžicka and J. Simmer describe a mathematically-based method for precise productivity measurements of autotrophic algae in cultivation, and S. Přibil and P. Marvan discuss the course of potassium uptake by cultures of *Scenedesmus quadricauda*. The following paper attempts to cover a difficult topic, that of dubious or incorrect designation of algal cultures used in experimental work: O. Lhotský reports a number of inconsistencies in the literature, especially concerning *Chlorella* but also involving species of *Chlorococcum*, *Ankistrodesmus*, *Euglena*, *Mesotaenium*, *Gomphonema*, *Anabaena* and *Polytomella*. He recommends a system of uniform designation of algal strains as suggested by Komárek in 1969. A second contribution by Hindák discusses biomass production of green algae in culture: constructional details of cultivation equipment are given and the results show that in both laboratory and field experiments a number of filamentous ulotrichalean genera (including *Ulothrix* and *Stigeoclonium*) give higher yields and simpler separation than the traditionally cultivated control, *Scenedesmus quadricauda*. This could be of great importance in commercial production. Finally, I. Šetlík, V. Šust and I. Málek describe a pilot plant for mass cultivation of algae in temperate zones in which the culture units can be used as glass-houses during the winter. Thus summer cultivation of algae is economically united with winter cultivation of higher plants, the latter probably in hydroponic units. Problems and advantages of this dual purpose scheme are considered, and the paper begins with an interesting general discussion of the principles of algal culture design.

It can be seen that this first number of *Algological Studies* is concerned with investigations of both a fundamental and applied nature and, while the primary use of

the journal will be to publish work from Třeboň, contributions are invited from other laboratories on any aspect of phycology. The standard of production of the journal is satisfactory, with clear printing on good paper. The matt finish of the paper does, however, suggest problems for studies where the results are essentially photographic. The half-tones included in the present number (chiefly photographs of experimental apparatus) are adequate for their purpose but would not be of sufficiently high quality for clear presentation of detailed electron micrographs. The chief value of the journal will doubtless be as an outlet for the rapidly increasing amount of work on algal biology in relation to the potentialities of the algae as a food source of worldwide importance.

GORDON F. LEEDALE

SPONGOLOGY

The Biology of the Porifera

Edited by W. G. Fry. (Symposia of the Zoological Society of London, No. 25.) Pp. xxviii + 512. (Academic: London and New York, May 1970.) 150s; \$22.50.

THIS new symposium in the Zoological Society series is a welcome addition. Study of sponge biology has been recently much neglected, and this collection of papers should do much to revive interest in this interesting group of animals.

The symposium, which was held in London in September 1968, was a particularly interesting one, mustering as it did, not only many of the world's authorities on sponges, but other biologists interested in cell adhesion and morphogenesis for whom sponges must have a special appeal. The papers range from fossil histories and affinities through subjects such as ecology and taxonomy of certain groups, cytology and ultrastructure. This volume is particularly welcome in that there is no modern general text dealing with sponges to which a general zoologist might turn for information, and this present work will undoubtedly provide a stimulus for further research. The principal sections are devoted to palaeontology, spicules and phylogeny, the ecology of certain groups or regions, cellular aggregation, integration of the cell types and morphogenesis. It is difficult to single out particular contributions as of particular interest for this is an individual matter. Dr Fry is to be congratulated in having achieved with such obvious success a difficult task of editing, and in producing a particularly useful index. This is a volume to be added to the shelf of every zoology department library. Certainly those with any interest in sponges cannot afford to be without it, and to those tempted into the field of sponge research, the bibliographies given in each contribution will provide a valuable starting point.

I regret that papers submitted in French or German remain in the original. These include important contributions by M. le Professeur C. Lévi, Madame O. Tuzet, Hr Dr H. Mergner, and M. le Dr R. Borojevic. It would be unrealistic to think that these chapters will be widely read by students; this is regrettable, and I think they should have been translated into English. Apart from this, Academic Press are to be congratulated in maintaining the high standard of typography and production achieved in this, as in the preceding titles of the series.

R. PHILLIPS DALES

LANGUAGE PSYCHOLOGY

An Introduction to the Psychology of Language

By Peter Herriot. (Methuen's Manuals of Modern Psychology.) Pp. 197. (Methuen: London, March 1970.) 42s.

IN recent years language has become a subject of central concern to psychologists. Some fifteen years ago it was possible to provide a survey of psychological studies of language within a coherent framework. A large range of

problems was at that time approached within a uniform associationist viewpoint; the differences between psychologists applying information theory to speech perception and those using concepts from animal behaviour to investigate how children learn to talk were chiefly ones of emphasis. This viewpoint has since been vigorously attacked by linguists for its failure to account for some of the most important properties of language. The subject matter is now in a very confused state: neither modifications to previous theories nor attempts to develop "performance models" from linguistic theory have had much success. This makes the task of writing a book today that is both an accurate survey and a coherent introduction to the subject an extremely difficult one.

Dr Herriot is one of the very few authors in recent years to attempt this. In *An Introduction to the Psychology of Language* he has produced what is a useful, accurate and well written survey of recent research on language. Perhaps, inevitably, in a book intended to be both short and comprehensive, certain sections tend to be little more than lists of technical terms, definitions and one sentence summaries of experimental studies. The range of topics discussed is a very conventional one and it is unfortunate that well known, but distantly related, work on memory is included at the cost of any reference to less familiar areas, such as bilingualism, second language learning or machine translation.

The title holds out the hope of an attempt to communicate what is exciting or challenging about the enterprise. In general, however, the author confines himself to providing a reference source, and readers for whom this book does serve as an introduction may well find the subject dull. For example, even the most critical will admit that contemporary work on generative grammars has produced fundamental and fascinating insights into language. The brief space devoted to this in the book is largely critical and a newcomer to the subject is likely to be puzzled that Chomsky and his colleagues have been so influential in the study of language. R. A. BOAKES

SELECTED TITLES

Titles in Medicine

Edited by Robert S. Goodhart. Vol. 1, No. 1. (Communico Inc.: Fairfield, New Jersey, March 1970.) \$2 per monthly issue; \$15 p.a.

IT is admirable that medical practitioners should be confronted with the existence of the medical literature and encouraged to read a little of it. This new secondary journal, which simply reprints the contents lists of about two hundred relevant periodicals, is to be sent without charge to "specific qualified physicians and surgeons" (presumably in the USA) and promises them—and other subscribers—twenty-four reprints of their choice for an annual fee of \$30.

The perceptive recipient will quickly realize that these services differ no whit from those offered by the Institute for Scientific Information's *Current Contents/Life Sciences*, which indeed would seem to be the superior (certainly handier) publication. ISI discovered that the labour of resetting contents lists could be obviated by the simple device of reproducing title pages photographically, which is not only cheaper but also more satisfying for the reader who sees the contents in their familiar format. ISI, moreover, has the grace to call its reprints "tear-sheets", thereby sidestepping some of the copyright problems thrown up by these ventures. And, finally, two hundred journals are just not enough: why not include *China's Medicine*, for example, for the benefit of those who wish to preserve a balanced outlook? And why should the practicing [sic] physician be denied a sight of titles of Letters to the Editor of *Nature*? From Vol. 1, No. 1 of *Titles in Medicine*, it seems that only the longer articles are worthy of his attention. J. H. MORRIS

Correspondence

Bode's Law

SIR,—Further to J. G. Hills's letter (*Nature*, **225**, 840; 1970) and that of John A. Antal (**227**, 642; 1970), your correspondents' comments on the following would be interesting.

Bode's law is geocentrically motivated because it uses as its basis the Earth's solar distance. It is increasingly inaccurate for planetary distances as the progression proceeds to the outer planets until by the time Pluto is reached the discrepancy is nearly 100 per cent.

However, as the table here shows, if the Jovian perihelion distance is used as a reference, it is possible to have an almost perfect prediction for planet solar distances by the simple expedient of using the arithmetical progressions of 2, 4 and 6 for the outer planets and $\frac{1}{3}$, $\frac{1}{5}$, and $\frac{1}{7}$ for the inner ones. Mercury and Pluto end the progressions with their highly elliptical orbits given by the factors 6 and 10 for Pluto's perihelion and aphelion and $\frac{1}{10}$ and $\frac{1}{16}$ for Mercury's.

Planet	Factor of Jupiter's perihelion	Perihelion/Aphelion Solar distance (million miles)	
		Actual	Predicted
Mercury	1/16	28.5	28.7
	1/10	45.7	45.9
Venus	1/7	66.7	65.7
		67.7	
Earth	1/5	91.45	91.9
		94.5	
Mars	1/3	128.5	153.2
		154.5	
Jupiter	1	459.8	—
Saturn	2	834.6	919.6
		937.6	
Uranus	4	1,699	1,839.2
		1,867	
Neptune	6	2,769	2,758.8
		2,817	
Pluto	6	2,766	2,758.8
	10	4,566	4,598

The significance of this simple arrangement is one that cannot be gone into here but the full explanation is contained in the publications *Genesis One, Two and Three*.

Yours faithfully,

D. ROOKES

c/o Ardilla Books,
29 Gloucester Crescent,
London NW1.

Library Pollution

SIR,—It has been established that the deterioration being caused by pollution can be arrested and even reversed if one is prepared to pay the cost. Cost however, needs to be related to benefit.

Deterioration may be less apparent in the case of books than in some other fields, but it is in fact insidious and the need for preservation treatment is most urgent. Moreover the wear and tear of frequent use increases the damage caused by atmospheric pollution. It is now generally conceded that excess acidity is the chief destruc-

tive agent apart from wear and tear and this acidity can arise either from present day methods of paper manufacture, when rosin alum sizes are used, or may be acquired from the sulphur dioxide content of a polluted atmosphere. So that apart from the repair of mechanical damage the deacidification of books and the prevention of further "pick up" of acid from the atmosphere are the most pressing needs.

Many effective processes for achieving these desiderata have been devised, but almost all of them are too slow and expensive to be used for the very large scale operations now necessary. As an illustration of the magnitude of the scale in question it is only necessary to cite the size of six well known and much used libraries.

According to the *World of Learning* for 1965/66 the following six libraries are believed to house about 44 million volumes distributed as follows:

	Million volumes
USA	
Library of Congress	14
University of California	6
Harvard	7
Yale	5
Great Britain	
British Museum	6
France	
Bibliothèque Nationale	6
Total!	44 million

Out of this total of 44 million volumes, assuming that half of these will be too acid to last more than 50 years, there is an obvious and urgent need to deacidify 22 million books before they deteriorate beyond repair and are lost to posterity.

The magnitude of this undertaking is enough to frighten the average librarian into *laissez faire* and this tendency will be accentuated by the apparent slowness of the deterioration which conceals the insidious nature of the damage.

If it is assumed that the 32 million volumes in the US deteriorate three times as rapidly as the 12 million of Great Britain and France (on account of the higher ambient temperature) and if a rate of deterioration in cash value equivalent to 3 pence per volume, equivalent to a useful life of 240 years for a book worth £3, is assumed, this small loss amounts in the aggregate to no less than £275,000 a year for the US alone.

Surely a small fraction of this cost spent on well directed research would lead at least to some effective first aid measures—or is the magnitude of the task too intimidating to stimulate the librarian and will it lead instead to a perpetuation of the present *laissez faire*?

There are signs that the librarians of the US are becoming alarmed at the implications of this wastage, but so far there seems little evidence that the British librarians are making any efforts to deal with this menace to our large libraries.

Yours faithfully,

W. H. LANGWELL

32 Copse Edge Avenue,
Epsom,
Surrey.

Ball Lightning

SIR,—I had just finished reading Powell and Finkelstein's article¹ and Altschuler's² chapter on Kugelblitz (ball lightning) when I came across the three recent reports³⁻⁵ on the subject in *Nature*. On May 15, 1970, at a point some 80 to 150 km east of St Louis, an aircraft in which I was a passenger was forced to fly into and through a thick dark storm-cloud mass. Extreme turbulence resulted in a rather violent movement of the wings of the aircraft (a Boeing 727). All this time the aircraft was descending, and an electrical display was lighting the surrounding clouds in a diffuse glow. The frequency of electrical discharges (no actual strokes were seen) increased with the increasing turbulence. At (what seemed) the moment of maximum turbulence and electric discharge, while the aircraft was still descending through the storm, a sequence of events took place that I list below. The whole took not more than 5 s, and I must admit that the order, save for numbers 4 and 6, is not necessarily chronological. 1, The turbulence ceased altogether. 2, The surrounding electrical discharges (glows) ceased altogether. 3, The wing stopped buckling altogether. 4, A white glowing sphere (ball lightning?) appeared on the port wing tip. I do not know if it was actually touching

the wing. Its diameter was less than 1 m and more than 10 cm. Its boundary was "fuzzy" and not distinct. 5, There was a soft "pop". 6, The ball lightning (?) vanished.

Regarding the accompanying noise (5) I recorded it at the time. Shortly afterwards my scientific upbringing and I both decided that an outside noise was not likely to be heard within a moving jet aircraft, and that my eye, seeing the ball go, insisted to my ear that it should do so accompanied by a noise. Nonetheless, I record it now, as I recorded it then.

Yours faithfully,

Obituaries

Professor S. Chapman

SYDNEY CHAPMAN, FRS, who died on June 16, made fundamental contributions to many subjects, especially gas theory, geomagnetism and atmospheric physics.

While still a Cambridge student, at Larmor's suggestion he began to work on the problem of viscosity, heat conduction and diffusion in a gas. This problem, posed by Maxwell and Boltzmann forty years earlier, had been solved only for two special types of molecular interaction; Boltzmann had stated that one must almost despair of a general solution. This was true if one sought an exact solution. An approximate solution, correct to any appropriate degree of accuracy, was, however, possible, and Chapman in 1915-17 provided such a solution, based on an equation of transfer given by Maxwell. Shortly afterwards (1917) Enskog independently gave a solution, based on the theory of integral equations. This, though more elegant in formulation, was essentially equivalent to Chapman's; thus one normally speaks of the Chapman-Enskog theory.

Chapman was especially concerned with applications of the theory to actual gases. The theory predicted two new phenomena, gaseous thermal diffusion and a converse thermo-diffusion effect. Chapman was delighted when Dootson in 1917 detected thermal diffusion and when Waldmann later demonstrated the converse effect; still more when Clusius in 1939, by his separation column, realized a dream of Chapman's, dating from 1919, that thermal diffusion might be used to separate isotopes. In 1922 Chapman was applying his results to plasmas (especially in stars); his work on the upper atmosphere, from 1925 on, relied on a background of kinetic theory. After the publication in 1939 of *The Mathematical Theory of Non-Uniform Gases*, written jointly with Cowling, he concentrated less on kinetic theory problems, though he reverted to them as new ideas struck him. It was fitting that the third edition of the book appeared just a month before his death.

When he left Cambridge, Chapman was appointed senior assistant at the Greenwich Observatory. He left Greenwich after only three or four years to devote himself to other interests; nevertheless, those few years in large measure determined his later research. At Greenwich he began by supervising the reconstruction of the magnetic

observatory. He found that magneticians were far readier to collect than to interpret data, and set himself to analyse geomagnetic variations. A visit from Schuster, a pioneer in the theory of geomagnetic variations caused by tides in the ionosphere, stimulated him to work both on the dynamo theory of the solar and lunar variations, and on tides in the upper atmosphere. Dyson drew his attention to the apparent connexion between solar flares and magnetic storms, so sparking off yet another series of investigations.

Chapman's research followed several lines, each systematically pursued over a number of years; sometimes he was working along several different lines at once. His work on the analysis of geomagnetic variations covered chiefly the years 1914-31; for it he was awarded the Adams Prize for 1927-28, and the work was later expanded into the two-volume epic *Geomagnetism* (1940), written jointly with Bartels. His main work on lunar atmospheric tides was spread over the years 1918-48. Before it, such tides could be securely inferred from barometric records only near the equator. Chapman isolated the tide from Greenwich records, and went on to determine its properties over the globe; to do so he had (especially with Miller) to devise methods of data processing at a time when mechanical aids were limited. This and the work of others was expounded in the recent book, *Atmospheric Tides* (1970), written jointly with Lindzen.

Chapman's work on magnetic storms began in 1919 with a paper, the theoretical part of which he later acknowledged to be invalid. During the next ten years he cautiously surveyed various aspects of the problem, but not until 1931 did he, in company with Ferraro, reach the idea that magnetic storms occur because streams of solar particles compress the geomagnetic field. This idea, predating observations of the magnetospheric cavity by thirty years, explained only the initial phase of a storm; not until after the discovery of the van Allen radiation belts could it be completed. Chapman shared with others in its completion, this time working with Akasofu (1961). He also introduced Akasofu to work on aurorae, which had long fascinated him, and took a lively interest in the solar wind, the continuous flow of which he had, in 1955, narrowly missed predicting.

In his Bakerian lecture (1931) Chapman gave the theory

of an ideal ionospheric layer, since named after him. He has also discussed the formation of ozone, other photochemical atmospheric problems, diffusion in the atmosphere and recently (with Kendall) noctilucent clouds. Fittingly, it was he who introduced the word 'aeronomy' for the science of the upper atmosphere.

He served as president for the Royal Astronomical Society and the International Union of Geodesy and

Geophysics, among other organizations. He was also chosen to act as president of CSAGI, the special committee for organizing the International Geophysical Year, a venture which he strongly supported and which owed much to his efforts. Officially he retired from his Oxford chair in 1953; in practice the effect was to double his activity and extend it over the world. His quiet, friendly, committed and wise counsel will be greatly missed.

Announcements

University News

Professor R. J. Kitz, chief of anaesthesia at the Massachusetts General Hospital, has been appointed Henry Isaiah Dorr professor of research and teaching in anaesthetics and anaesthesia at **Harvard University**, in succession to **Professor Henry K. Beecher** who will become Henry Isaiah Dorr professor emeritus. **Mr C. Richard Taylor**, of Duke University, has been appointed first director of the **Concord Field Station of Harvard's Museum of Comparative Zoology**.

The following appointments have been made in the **University of London**: **Mr J. N. Britton**, to the Goldsmith's chair of education tenable at the Institute of Education and attached to Goldsmiths' College; **Professor B. R. Rabin**, to the chair of biochemistry, University College; **Dr G. F. M. Russell**, to the chair of psychiatry tenable at the Royal Free Hospital School of Medicine; **Mr G. N. Walton**, to the chair of nuclear technology at the Imperial College of Science and Technology; **Dr D. V. Bugg**, to the chair of nuclear physics, Queen Mary College; **Professor S. J. G. Semple**, to the chair of medicine tenable at the Middlesex Hospital Medical School. The title of professor of entomology has been conferred on **Dr Reginald F. Chapman**, in respect of his post at Birkbeck College, that of professor of rock mechanics has been conferred on **Dr Evert Hoek** in respect of his post at the Imperial College of Science and Technology, and that of professor of chemistry has been conferred on **Dr A. J. B. Robertson**, in respect of his post at King's College. The title of Emeritus professor has been conferred on the following: **Professor E. Boyland** (biochemistry, Institute of Cancer Research); **Professor F. Brailsford** (electrical engineering, University College); **Professor F. C. Champion** (experimental physics, King's College); **Professor F. E. Camps** (forensic medicine, London Hospital Medical College); **Professor G. W. Causey** (anatomy, Institute of Basic Medical Sciences); **Professor S. J. De Navasquez** (pathology, Guy's Hospital Medical School); **Professor S. E. Dicker** (physiology, Chelsea College of Science and Technology); **Professor F. Goldby** (anatomy, St. Mary's Hospital Medical School); **Professor J. Greig** (electrical engineering, King's College); **Professor W. J. Hamilton** (anatomy, Charing Cross Hospital Medical School); **Professor H. R. Hewer** (zoology, Imperial College of Science and Technology); **Professor A. Kekwick** (medicine, Middlesex Hospital Medical School); **Professor N. F. MacLagan** (chemical pathology, Westminster Medical School); **Professor Sir John Randall** (biophysics, King's College); **Professor J. W. Smith** (chemistry, Bedford College); **Professor R. S. Stacey** (pharmacology and chemotherapeutics, St Thomas's Hospital Medical School); **Professor Lord Stamp** (bacteriology, Royal Postgraduate Medical School); **Professor J. S. Wilkie** (history and philosophy of science, University College).

Appointments

Dr A. F. Spilhaus has been appointed executive director of the **American Geophysical Union** in succession to **Dr Waldo E. Smith**, who has retired after 25 years of service with the organization.

Professor George W. Beadle, University of Chicago, and **Mr Thomas H. Coulter**, Chicago Association of Commerce and Industry, have been appointed co-chairmen for the 1970 meeting of the **American Association for the Advancement of Science**.

The first three senior appointments to the new **Medicines Inspectorate** have been made: **Mr A. G. Fishburn** is to be principal medicines inspector and **Mr R. Baker** and **Mr W. P. Jones** will be senior medicines inspectors. Mr Fishburn was formerly with the ICI Pharmaceuticals Division, and Mr Baker and Mr Jones with Parke Davis and Cyanamid, respectively.

Miscellaneous

To mark **Professor H. R. Hewer's** golden jubilee and retirement from the chair of zoology at Imperial College, a dinner will be held at the college on October 1, 1970. A presentation will be made at a sherry party before the dinner. If any of Professor Hewer's friends or students have not received details of the celebration, they should contact Dr D. M. Kermack, Zoology Department, Imperial College, Prince Consort Road, London SW7.

Sabbatical Itinerants

From the issue of September 5, entries of this kind will appear among the classified advertisements and will be charged for accordingly. Copy should be addressed to T. G. Scott and Son Limited, 1 Clement's Inn, London WC2A 2ED

Exchange: Cork (Ireland) architect taking one year postgraduate course at the University of Edinburgh wishes to exchange furnished house in Cork in own grounds of 2 acres, 3 miles from city centre and university, for house in or near Edinburgh from October 1, 1970, to June 30, 1971. Please contact G. F. McCarthy, Oldwood, Rochestown, Co. Cork, Ireland.

Wanted: Comfortable 4 bedroomed home in Oxford area from March 25, 1971, to August or September 1971, for considerate family with 4 children, ages 15-20. 5 bedroomed home available in Seattle. Please contact Professor B. S. Rabinovitch, Department of Chemistry, University of Washington, Seattle, Washington 98105, USA.

British Diary

Wednesday, September 2

132nd Annual Meeting (eight days) British Association for the Advancement of Science, at Durham.

Man/Computer Interaction (three-day conference) Institution of Electrical Engineers, and the Institution of Electronic and Radio Engineers, at the National Physical Laboratory, Teddington, Middlesex.

Sunday, September 6

RF Electrical Measurement Practice (thirteen-day vacation school) Institution of Electrical Engineers, and the Institution of Electronic and Radio Engineers, at the University of Kent, Canterbury.

Monday, September 7

Basic Concepts in Modern Control Theory (five-day vacation school) Institution of Electrical Engineers, at the University of Birmingham.

Control Mechanisms of Growth and Differentiation (five-day symposium) Society for Experimental Biology, in conjunction with the Society for Developmental Biology, at Eliot College, University of Kent, Canterbury, and Wye College (University of London), Wye, Ashford, Kent.

Computational Physics (three-day conference) Institute of Physics and the Physical Society, at Imperial College, London SW7.

Third International Broadcasting Convention (five days) Institution of Electrical Engineers, and the Institution of Electronic and Radio Engineers, at Grosvenor House, London W1.

HOW TO BUY NATURE

Volumes start in January, April, July and October, but subscriptions may begin with any issue.

The direct postal price per subscription for one copy of NATURE each week is:

*12 MONTHS (52 issues and 4 indexes)

Great Britain and Eire.....	£14 0 0 each
United States of America..... (by air freight).....	\$48 each
Canada..... (by air freight).....	\$52 each
Elsewhere overseas by surface mail.....	£14 0 0 each

(Charge for delivery by air mail on application)

*Shorter periods *pro rata*. (Minimum three months.)

Is there Time for Thinking ?

IN characteristically different ways, Lord Todd, President of the British Association this year, and Professor John Ziman have raised at the British Association questions about the institutional structure within which science must be carried on in countries such as Britain. Lord Todd is concerned (see page 988) to argue that there is a need to match the educational system more sensitively to the needs of professional scientists and to the frequently conflicting needs of the young people entering into higher education. Professor Ziman is rightly alarmed that the character of scientific work may be damaged by some of the institutional forms which have emerged or which may emerge, but at the same time anxious that people should more explicitly acknowledge the importance of the conventions which keep professional behaviour within seemingly bounds and which have given science its reputation for integrity. One of the oddest features of the development of science in the past few years has been the tendency to take these institutional forms for granted. The title of Lord Todd's address—"A Time to Think"—is intended as a plea that the time has come for a reorganization of the educational reappraisal of what society can expect of scientific work, and nobody will quarrel with him by denying the need for change. The question is whether there is time enough.

The defects of the educational system—not merely in Britain but wherever universities offer science as a part of their curriculum—have been plain for donkeys' years, and one of the pathological signs that Professor Ziman might have included in his catalogue is the shameful way in which academics have taken these educational problems seriously only since what is called the drift away from science made them alarmed that the need for university teachers of science might one day disappear. Even when students were fighting to get into the laboratories, however, it was plain that the structural defects of the undergraduate curriculum had become an impediment to education in the broader sense. It is a great source of shame that so little should have been done, in the past few years, to put this right.

What needs to be attended to? First of all, there is the important question of entry requirements to the universities. Wherever dons are gathered, it is comparatively easy nowadays to win agreement that students and universities would be better off if secondary education (in Britain) were more liberal. Even chemists will sometimes be ready to admit that their students would be able to survive the rigours of university education in chemistry without first having been through exactly the same hoops at school.

Moreover, there has in the past few years been a kind of understanding between the universities and the schools that there should be negotiated the basis for a broader sixth-form education—the common assumption is that when the protracted negotiations between the Schools Council and the Standing Conference on University Admissions are eventually completed, sixth-formers will be expected to prepare themselves in five subjects, not simply three as at present. This is a meagre reform for which to wait so long. And there is very little hope that the new pattern of school studies and university entrance requirements will carry the system forward to the point at which a student's work at university or elsewhere in the higher educational system may be quite unrelated to his work at school. The result will be not merely needless specialization at schools and the loss of potentially bright people to potentially rewarding careers by the accidents of their arbitrary choices in extreme youth, but also a reinforcement of those pressures, already far too powerful, which isolate one part of the educational system from another, thus diminishing the power of the academic world to stimulate itself. It goes without saying that the same requirement that higher education should be open only to those who by demonstration in advance are least in need of it perpetuates the educational privilege of the better schools. It is a scandal that the universities as a whole and university teachers of science in particular should have been as complacent as in the past few years in tolerating this state of affairs.

The internal defects of higher education have similarly been neglected for too long. Again it is something of a scandal in Professor Ziman's delicate sense that interest in reform has been awakened largely by external pressures. In Britain, for example, the Committee of Vice-Chancellors seems to have given lukewarm support to the notion of a two-year degree course chiefly because this seems to offer some relief from the continually mounting pressures of the demand for more and more higher education. With encouragement from the government (anxious to save a little money as well as to make the system grow), the Vice-Chancellors gave timid support to the concept of a two-year university course as a preparation either for vocational training of some kind or as a preparation for more advanced scholarship. But the device which now seems desirable on the grounds of expediency has been educationally sensible for a long time. Professor Brian Pippard, for example, made an eloquent argument in favour of such a scheme some time ago (*Nature*, **219**, 1307; 1968). The way things have turned out in Britain, there is good reason to believe that the usual

three-year course for undergraduates contains too much teaching for many people but that it is certainly too skimpy as a preparation for a career in science as such. Educational arguments are sufficient to force this conclusion.

Important questions about the character of university education in science are also habitually overlooked. Needless specialization is rife. Chemists, for example, are taught thermodynamics as if it were a discipline quite distinct from that drummed into physicists. At many universities, it is still possible for an undergraduate to be taught biology well, while remaining innocent of the mathematical techniques which have already been tools of the trade. And in many universities, attempts are being made to give courses what their designers fancy will be greater relevance by throwing in a few bits and pieces from courses in economics or management. Altogether, there is too little care for embodying in university courses the qualities of an intellectual kind that make scientific work as such intellectually exciting. In many ways, it is a surprise that university courses in science have retained some attractiveness for young people when so little has been done to elevate them above the status of compendia of manipulative techniques.

The same is true of higher degree courses at the universities. In the past few years, research has been made almost a mockery of what it might be by the mindless growth of many graduate schools. Professor Ziman points out that the PhD process has become too automatic. The Western world abounds with university departments in which an important piece of equipment, an NMR machine perhaps or a mass spectrometer, becomes the means by which dozens of young men and women go through the motions of research, fill out their theses and, in due course, are moved one rung up the ladder. Because snobbishness is such an easy trap in discussions of this kind, it is important explicitly to acknowledge that the old-fashioned PhD system had such serious flaws that it is probably now unworkable. It is too much to ask that every candidate for a higher degree should carry out some entirely original piece of research, more or less unaided by his superiors. Indeed, it is important now to recognize that the higher degrees are means by which people are trained in the techniques of research and are at the same time provided with opportunities—which many people seize—to become scholars in the old-fashioned sense as well. Among educationists, it should now be a burning question to know how these occasionally conflicting needs should be satisfied in modern universities. The chances are that any pattern of advanced work that seemed more appropriate than the present would be one in which there were more incentives for young people to make original contributions to science outside the framework of what has become the conventional pattern of success. Is it too much to ask that a man's achievement should be marked by the influence which his work has on other people's work, and not by the flimsy signs of that influence consisting of the appearance of scientific

papers in the journals and by the award of appropriate degrees?

The literature is a splendid embodiment of Professor Ziman's little pathologies. Among scientists, it tends to be assumed that the scientific literature exists for the benefit of authors, not readers. The result is that much of the literature is unread except by the growing army of abstractors, cataloguers and the like. Those who contribute to the published literature are sometimes simply concerned with establishing priority for a discovery, the significance of which it is too soon to assess. Often, the obscurity of a paper can be traced directly to the inadequacy of its preparation; yet is it not an offence against the doctrine that the scientific literature should be the living embodiment of the accumulation of discovery that some of it should, with the knowledge and consent of its authors, be too obscure to be understood? Professor Ziman might have added to his list of the little weaknesses of professional science the temptation for people to hug their discoveries to themselves—Hooke and his anagrams are a good illustration. But is there not in the defects of the scientific literature in modern times a powerful streak of this unwillingness to be fully understood? And is that not at least a partial denial of the nature of intellectual life, in which deeper understanding usually springs from attempts by honest people to understand what other people have to say?

Professor Ziman is right, of course, to emphasize that to make too much of these defects would be to underestimate the essential health and integrity of the profession of science. That is true. Too much crying of stinking fish may indeed provide unwarrantable excuses for mindless criticism of the profession of science. There is, however, a real dilemma to be resolved. If, for the sake of not giving hostages to fortune, too little is said about the structural defects within science, there will be no hope that they will ever be repaired. This is why even such apparently unseemly matters as the bumbledom of the national academies, or the arbitrariness of the system for awarding Nobel Prizes, need to be talked about in public if the institutions concerned are not themselves to be overwhelmed by the reputation for anachronism. But criticism, however constructive, cannot by itself be a way of mending what is wrong. The more urgent need is that there should be a recognition among practising scientists that the scientific life is an intellectual life, not merely an extension into the universities of modern business. To admit this does not in any sense imply that science has nothing to contribute towards prosperity and public health—most probably the shoe is on the other foot, for a more vigorously intellectual profession of science would be an even more prolific source of innovation. Certainly it could hope to become again the focus for the intellectual idealism of the young people who used to throng into the laboratories. The most serious danger now is that with the mounting pressures from outside—the demands for economics and for relevance, whatever that may be—there may be no time left for thinking.

Putting Power Stations where they Belong

THE row about the siting of a new electricity generating station for New York, settled by one of Mr John Lindsay's characteristic compromises (see page 992), is more than a local squabble or even a special feature of what remains the most remarkable of all cities. In one way or another, most modern cities find themselves hard pressed to know just how to keep themselves supplied with electricity. In many places—London is all too obvious an example—the solution has been to build generating plants as close as possible to the points at which the electricity is consumed. The result has been either disfigurement or needless air pollution or a combination of both. It follows that there should be a deliberate attempt to isolate the lessons that can be learned from the maladroitness for the building of the Astoria power plant in New York, for even if the mayor has for the time being made sure that the Astoria plant will be the last in New York to burn fossil fuel, his writ does not run elsewhere.

The lack of forward planning is perhaps the most obvious and the most serious defect of the scheme which is now to be half implemented, and it is only fair to say that the utility company, Consolidated Edison, is not entirely to blame. For several years the company has been hindered in its schemes for building power stations for New York by considerations for the quality of the environment. In the early sixties, for example, the company was prevented from building a nuclear power station more or less across the river from the United Nations headquarters and even if, now as then, the company seems to have been foolishly willing to mix technology and people's living spaces, its arguments about the urgent need of generating capacity have been plain enough. The prospect earlier this summer that there would not be enough generating capacity to keep the air conditioning sets in operation, which happily has not materialized, has been a powerful reminder that cities are unworkable without electricity, and that it is necessary to plan for future growth three or even five years ahead. So much everybody will concede.

But is it necessary to meet the growth of a city's need of electricity by building power stations on the spot? This is the most constructive of the questions raised in the protest about the Astoria power station in the past few weeks. The answer, of course, is that there is no technical reason why a city even as large as New York should not be supplied with electricity generated at a remote site. To be sure, the cost of transporting electricity over distances of the order of some hundreds of miles is not negligible, especially when the alternatives are power station sites that can be supplied cheaply with fossil fuels by sea or river; yet the cost is at the same time not outrageous. In the United States, where the interconnexion of the electricity generating systems is not nearly as well developed as in Europe and where

the economic advantages of interlinked capacity have not been exploited to the full, it would be surprising if the real extra cost of building power stations away from cities were as much as an extra 10 per cent. The way in which many utility companies plan to make money by generating electricity at remote nuclear installations is a sufficient proof that distance need not be an insuperable obstacle. In this sense, Mr Lindsay is entirely right to have insisted, in his agreement with Consolidated Edison, that the local utility should develop its distant connexions. That is a step that other city authorities could usefully take.

It is entirely within the bounds of possibility that the demand for electricity in a city such as New York could be substantially reduced by proper design. The question has received no attention worth speaking of, but the point has probably now been reached at which buildings might be designed to be kept comparatively cool in summer without making such a large demand on the air conditioning supplies. Instead of throwing up their hands in horror at the condition of the modern city, people should pay some attention to problems like these.

100 Years Ago

NOTES

A WEEK or two ago we announced a rumour to the effect that the Government had refused to allow a ship to convey the eclipse observers to Spain and Sicily next December. The rumour was too well founded; the Government has actually refused to tell off a ship for this purpose. This decision in the teeth of the plainest precedents requires no comment on our part; in fact, it is beyond all comment, it is astounding. We are enabled to announce, however, that the American Government, more enlightened than our own, are making extensive preparations; and upon the results of their labours and those of the Continental Governments Englishmen must therefore fall back, in a research which is eminently English. The Americans will send three corps of observation, to be stationed respectively at Malaga, Sicily, and some place in Turkey most available for making the best scientific records and views. One of these corps will be sent from the Naval Observatory, and the other two will be composed of the most scientific men in the country, including the professors from Harvard University. Before the war broke out it was arranged that Rear-Admiral Glisson should extend to the corps at Sicily all the aid and co-operation in his power. But the original plan has been spoiled for the present by the troubles in Europe, Admiral Glisson being obliged to move his squadron to the Baltic for the protection of American commerce in that vicinity.

OLD WORLD

BRITISH ASSOCIATION

Thinking about Education

THE British Association for the Advancement of Science opened in Durham last Wednesday with an address by the association's president, Lord Todd of Trumpington. The burden of Lord Todd's message is that "while science and technology have been bringing about vast changes in our material existence at an ever-increasing pace we have failed to match them with appropriate social and educational changes". The symptoms of this failure are "the frustration evident among young people" and a disillusionment with science which is sharpened by concern about pollution and deterioration of the natural environment.

Such a theme, as Lord Todd himself points out, is hardly new, but his chief concern is that appropriate steps should be taken to remedy the situation, and that is why the theme bears repeated discussion from all angles. This, according to Lord Todd, "is a time to think", especially about the structure and content of the education system.

Education holds the central position in Lord Todd's thinking for a variety of reasons, but mainly because educational patterns and social attitudes go hand in hand. Until school and university curricula are taken out of the straitjacket of specialization, and until natural science is recognized "as much a branch of culture as music, literature and the arts and not in any sense a subject for the specialist alone", it will always be viewed with scepticism. There will therefore be little hope of creating a scientifically conscious democracy capable of taking rational decisions about science policy until society, through education, is made aware of the nature of science.

The place to start, according to Lord Todd, is in the secondary schools, by broadening, curricula and putting an end to early specialization. But this will have little effect as long as the virtues of traditional university education are emphasized at the expense of other types of tertiary education. One of the chief malaises of British education in Lord Todd's view is that too many students are clamouring at the doors of the universities for an education to which many of them are unsuited. It is therefore not only unrealistic but also positively damaging to suppose that the official estimates that 450,000 students will be accommodated in British universities by 1980 mean that many more students will be receiving the benefits of university education. "What a large proportion of that 450,000 ought to pursue is some other form of higher education with a different and greater vocational bias."

The trouble with regarding university education as the ultimate academic aim for which every school-child should strive, according to Lord Todd, is that university graduates ultimately end up in jobs for which their training is completely unsuitable, and they become frustrated. This frustrated white-collar class is "in part responsible for the so-called 'drift from science'". Lord Todd therefore believes that urgent thinking is required, before the debate about the future of higher education draws to a close.

COUNTRYSIDE

Boost for Linear Planning

by our Planning Correspondent

FROM the date of its nationalization (January 1, 1948) to December 31, 1968, British Railways closed 5,618 route miles (9,041 km) of railways in England and Wales. In other words, as the Countryside Commission so vividly describes in a new report, the area of railway land which has been falling into disuse each year is roughly equivalent to the land requirements of a new town of 80,000 persons (*Disused Railways in the Countryside of England and Wales*, HMSO; £1). Much of this railway land remains derelict, and only about a third of the mileage on the market between 1948-68 was actually sold (see Table 1). Obviously in a country as crowded as Britain, such land ought to be put to use again, but the disposal of disused railway lines seems to be fraught with difficulties according to Dr J. H. Appleton, who prepared the report for the Countryside Commission.

Table 1. RECENT RATES OF CLOSURE AND SALE OF RAILWAY IN ENGLAND AND WALES

	Length closed (km)	Length sold (km)	Excess of length closed over length sold (km)
1965	1,002	204	798
1966	1,209	449	761
1967	568	488	80
1968	641	528	113
1965-68	3,420	1,669	1,752

Part of the problem is that the use of railway land is limited to a large extent by its physical characteristics—its linear form, gradient, curvature and the like—and its sometimes complicated relationship with the adjacent land. A further difficulty is that, at present, while the government requires the British Railways Board to offer the land first to local planning authorities, the authorities usually decline to buy it and British Rail then offers it elsewhere to the highest bidder with the result that land is often sold piecemeal. The whole procedure, according to Dr Appleton, is complicated, often protracted, rarely integrated, and hardly in the public interest as a whole. But this land-use problem is not one, Dr Appleton says, that can be solved by a blanket decision that converts all disused railway lines into agricultural land, long-distance footpaths, bridleways or roads, however worthy these potential uses. Each stretch of railway land needs to be judged on its own merits and costed efficiently, although its disposal must also be seen in the wider context of a general land-use policy; for example, some lines might be integrated into an existing reclamation scheme.

Dr Appleton suggests therefore that the disposal of disused railway land should be taken out of the hands of British Railways and passed to some new body which could look at the matter in a wider context. Alternatively, the local planning authorities could be responsible, or even the Countryside Commission which, given more staff, could coordinate policy. Although there will continue to be conflicts of interest (particularly between agricultural and recreational uses), Dr Appleton believes they would be reduced if decisions were logical, if the public were involved, and also if they were consistent with declared land-use policy.

DEFENCE

A Hole in Skynet

from a Correspondent

AN inquiry is now going on at Cape Kennedy as to the cause of the disappearance of the Skynet 1 defence communications standby satellite built under contract for the British Ministry of Defence by Philco-Ford. The successful launch by a US Air Force Delta rocket took place on August 19, but a week later when the satellite was due to be "kicked" into its 30,000 kilometre geostationary orbit above the Indian Ocean, telemetry signals failed during firing of the apogee motor (which performs the final orbital manoeuvre). The result is that the satellite may well be in its correct orbital position without anyone being the wiser. No contact has been obtained since, although hopes of tracing the satellite (presumably by radar) have not entirely faded. If traced, it is possible that the satellite could still perform its purpose—acting as a high-speed voice link for the armed services between England and the Far East if its predecessor, launched last year, ever becomes out of action. At present, the first Skynet 1 satellite is still fully active and there is a contractual bonus for each additional year in which it keeps working, up to 5 years.

Specifications for a revised, second generation satellite link for the Ministry of Defence, called Skynet 2, have already been drawn up, this time with British contractors in view. The first replacement by Skynet 2 is called for in 1973. Hawker-Siddeley Dynamics and GEC are preparing preliminary design studies, one of which is expected to be chosen later this month.

Various questions now arise. If the second Skynet 1 proves irretrievably lost, will the Ministry of Defence be able to soldier on for up to three years without a standby until Skynet 2 is ready? (It has managed without for nine months so far.) Is any compensation payable in the form perhaps of a free replacement launch by the Americans? An apogee motor is integral with the satellite, though it may be considered part of the launch. Is western security considered at risk? Upon this, as much as upon the results of the current inquiry, may depend the terms on which a further Skynet 1 is, or is not, speedily in orbit.

BRITISH SPACE

Dead-end Rocket

THIS week Britain has been shamefacedly and unsuccessfully trying to enter space with a rocket for which there is no future. Even the space hawks have been showing embarrassment, not joy. A satellite could have been launched by a British rocket as much as ten years ago, they were saying before the firing. Seen from Britain, the preparations of the Black Arrow rocket on the launch pad at Woomera seemed more like a wake than a step through a new frontier, and the delays, first of all because of a fault in the tracking station at Gove, northern Australia, only prolonged the agony.

Black Arrow's genealogy begins with the Black Knight research rocket that was first fired twelve years ago, with an injection of engine technology from the Blue Steel stand-off bomb. On average one Black Arrow rocket is being made each year in a programme that is costing about £3 million per year but is expected

to rise to about £5 million during the next five years. The cost of this week's rocket and its payload is believed to be in the region of £1 million. This expenditure, the Ministry of Technology would say, will buy prestige that will help the electronics industry, even though satellites have already been launched by five other countries including the arch-competitor, Japan. Later Black Arrow launchings of technological satellites to test new solar cells and the like, Mintech says, "will represent a major step in the development of application satellites". Yet it is inconceivable that Black Arrow could ever launch a satellite into a geostationary orbit, and this is where communications satellites have to be. Even with four Skylark rockets strapped to the first stage, a scheme being considered to double the payload to about 400 lb., Black Arrow could not carry a geostationary satellite and the additional motor to get it there.

What then will Black Arrow achieve? At best it has kept Britain's hand in, an insurance policy to mature when British space policy extricates itself from the two stools between which it has fallen. Either Britain will have to go in with the Europeans, in a more full-blooded scheme than has existed so far, to exploit the technology that is available for scientific and commercial use, or remain at the present level, launching satellites that belong to the first decade of space research. Space technology has gone beyond the Black Arrow stage to heavy communications satellites and the observatory type of scientific satellite.

URANIUM

How Much Ore in Scotland?

IT would be premature at this stage to see the makings of a new "uranium rush" in the disclosure last week that deposits of uranium ore in northern Scotland are substantially more widespread than had hitherto been considered. Although a survey for uranium, being carried out for the Atomic Energy Authority by the Institute for Geological Sciences, has shown indications of significant quantities of uranium minerals around Ousdale, Helmsdale and Brawlbin in Caithness there is still no hint of commercially viable deposits on the evidence so far.

In one area near Ousdale, however, a zone of something over a kilometre in length was located containing quantities of uranium ore. Anomalies in surface and below-surface radioactivity were detected in several other neighbouring areas and in their first report of the findings Dr S. H. U. Bowie, Mr D. Ostle and Dr M. J. Gallagher point out that there is certainly enough evidence to warrant further investigation of these areas.

The Atomic Energy Authority are looking to establish mining interests to follow up this challenge. Although the British nuclear power industry spends at present only about £7.5 million a year on uranium concentrate this figure is increasing all the time, and the AEA are obviously conscious of the long-term saving which a substantial uranium find would offer.

The survey reported by Dr Bowie and his colleagues was the first part of a five-year reconnaissance announced by the Minister of Technology in March 1968. It is being carried out by a team of twelve qualified staff on a grant of £250,000. One of the interesting features is the amalgam of techniques

being used to locate the uranium deposits. As much of the area is covered by a layer of peat, detection of radiation by scintillation counters is of only limited value. In addition therefore a technique was used which involved boring into the peat and measuring the concentration of radon in the "ground air". Variations in the radon and gamma ray intensities give an indication of the extent of the uranium deposits, but it is pointed out that probes down to several hundred feet will have to be employed before any firm estimate can be made of the amount of uranium present.

MEDICINE

Watching for Carcinogens

THE International Agency for Research on Cancer has concentrated on environmental cancer biology since it was set up by the World Health Organization in 1965, and its decision now seems to have been an excellent example of foresight. With programmes that cover hazards from asbestos to pesticides, the agency is well placed to feed the massive interest that has since developed in what the environment can (and cannot) inflict on the body, as is clear from its latest annual report. What is more, the report stresses the need to deal chiefly with human disease patterns "as long as our knowledge of comparative carcinogenesis and toxicology in animals and man remains insufficient to permit extrapolation", for "no alternative methods have been established permitting a definite assessment of environmental hazards to man". Those who would cry wolf at the sight of a dead rat might do well to consider this message.

On a budget of just under \$2 million, which is contributed by nine participating states and by WHO, the agency runs its own laboratory in Lyons—where a new building is due to be completed soon—and backs research in national centres; it has set up regional centres in Nairobi, Singapore and Jamaica, and also offers fellowships for training and for travelling. Its aim is to work on international cancer projects which as far as possible do not clash with what its participating states are doing on their own account, although it recognizes its usefulness as a neutral source of second opinions in cases where national sources are controversial or inadequate. In general its role is to gather new information, thus taking part in a convenient division of labour with the WHO Cancer Unit which is responsible for treatment and control.

The epidemiological section of the agency continues to digest statistics and produce uncomfortable correlations. Cancer of the oesophagus in Curaçao seems to be related to the consumption of a hot maize porridge; laryngeal cancer has a high incidence in Thailand and may turn out to be not unconnected with a local cigar which contains uncured home-grown tobacco and tree bark in roughly equal proportions; and there are even hints of a correlation between cancer of the colon and rectum and the consumption of meat. In the future, the environmental emphasis is expected to continue. The agency is hoping to increase the number of participating states, and intends to build up the network of collaborating laboratories engaged in specific programmes with different population groups; but in spite of the training it offers, it is still having trouble in attracting enough good staff to Lyons.

CONSUMERISM

A Fish by Any Other Name . . .

To sell a plaice as a sole may not seem the gravest of crimes, but is nevertheless to be illegal from next year. Techniques for finding out what the species of a fish really is are consequently being made much more subtle, to judge by the report for 1969 of the Torry Research Station in Aberdeen (HMSO, 7s). By an electrophoretic method which identifies the water-soluble proteins from a small piece of flesh, the fish fraud can now be tracked down even if his fish have been skinned, filleted and cooked. For the moment, however, tinned fish will escape this net, because the proteins are changed too much in processing.

Another advance on the human nose is embodied in simplified kits that have been devised at Torry for assessing the freshness of wet fish. Their object is to measure the concentration of hypoxanthine, which begins to form in the flesh of a fish as soon as it is dead; an extract of the flesh is treated with reagents whose colour disappears if the fish is off. Prototype kits are soon to go on trial, but before they can be used regularly the amount of hypoxanthine that is to define an unacceptable fish will have to be investigated more precisely.

Measuring the quality is particularly important for fish that are frozen at sea, because they are sometimes kept frozen for several months. To determine the best way of handling catches, Torry staff have been comparing different methods that are used on board commercial trawlers. Both the delay before the fish are frozen and the temperature at which they are kept seem to be crucial; one promising approach is to use refrigerated sea water to chill the fish first. According to a survey of the consumer end of the fishing industry, however, sea frozen fish are more consistently of high quality than wet fish, and barely more expensive.

About half of the British catch is converted to fish meal for feeding animals. This proportion, however, consists largely of surplus fish and offal from fillets, and the director of the Torry Research Station, Dr G. H. O. Burgess, argues in the report that Britain would do well to develop an industrial fishery, for in 1968 the country imported about six times as much fish meal as it produced. The value of the imports, together with imported fish oil, was £41 million.

Electrophoretic "fingerprints" of fish species: 1, cooked lemon sole; 2, cooked Dover sole; 3, raw lemon sole; 4, raw Dover sole.

Too Much Astronomy at the IAU

IN the end the International Astronomical Union meeting at Brighton was a roaring success. The right level of unobtrusive efficiency soon replaced the casual organization during the registration period that had looked ominous for the 2,300 who attended. Obviously many people at the University of Sussex and the Royal Observatory nearby at Herstmonceux had been taking time off from their research to see that things ran smoothly. Even a readable newsletter was printed daily for the participants.

The danger now is that the union's executive will have been lulled into thinking that general assemblies will always be like this. At the University of Sussex there were often eight meetings, sometimes ten, running at the same time. That sort of thing takes some organizing, and the union may not be as lucky with its hosts another time. As it happened, the question whether the interval between general assemblies should be increased from three to four years was eventually shelved. That would have been no answer anyway to the overlapping meetings, too many papers in too short a time, and overcrowded lecture rooms. Nobody wants to restrict the list of people who attend, but the alternative seems to be to split the general assembly into several symposia. So long as there are astronomers like Fred Hoyle, however, taking part in the sessions on cosmology and on the development of the solar system, subdivision of the general assembly goes very much against the grain. As it is, it is surprising how most astronomers are managing to keep up with all branches of their subject when other sciences have long ago fragmented. At Brighton last week it never seemed odd to see, for example, a radio astronomer attending a meeting on the lunar ephemeris, or an atmosphere scientist listening to the debate on pulsars. The IAU will have to go on with its general assemblies in roughly their present form as long as it can. Now is the time to ask, however, that the number of separate meetings be made fewer to give everyone a fair chance of getting to the meetings they want to hear.

But one thing that was clear from the Brighton meeting was that astronomers hate astropolitics. That was part of the reason why the first meeting of the new commission on cosmology was packed to overflowing—the other commissioners were involved in business meetings. On the question of the interval between general assemblies the buck was passed to the new executive committee. And it was disturbing how the financial implications of having two general assemblies in 1973 instead of one was glossed over. That was the solution to the impasse over whether the IAU should accept a longstanding invitation to visit Sydney, Australia, or a late invitation from Poland to celebrate the Copernicus anniversary with a meeting in Warsaw. By a vote of 28 to 14 the IAU accepted the Australian invitation, but with what is to be called an extraordinary general assembly in Warsaw to appease Poland. The meeting in Poland will follow the main general assembly, in the first half of September 1973, and will be limited to six topics—planetary and galactic dynamics, cosmology, a topic from relativistic astrophysics, the origin of the planetary system, a topic from stellar evolution, and a meet-

ing on the history of astronomy to be held at the birthplace of Copernicus.

It would be impossible to predict what will be the talking points in 1973. No doubt the radio astronomers will still be pressing for better protection for the radio astronomy bands. By then optical astronomy may well have been surpassed in precision by radio astronomy. Pulsars will certainly still be an important topic, because even if the emission mechanism is understood by 1973, it is unlikely that the knottier problems concerning the interior structure of neutron stars will have been unravelled by then. And it will be interesting to see how much more will have been learned about the Moon and planets. It now seems quite on the cards that the Apollo programme will not last long enough to do all that the planetary scientists want.

Astronomy after 1975

IN a pamphlet handed out at the Brighton meeting, the Science Research Council has let slip some of its thinking about the development of astronomy in Britain during the next decade. What is being debated is how to spend the astronomy budget, now standing at around £3 million for ground-based astronomy, when the two big projects now under way are completed. The 5 km aperture synthesis radio telescope at Cambridge will be the first to be finished, in August next year, followed by the 150 inch Anglo-Australian optical telescope in 1974. Still hanging fire, of course, is the project for a 400 foot radio dish to be built in North Wales.

Looking five years ahead, there is a plan to enter the field of astrochemistry with a 30 metre dish able to work from 3 cm down to 1 mm. This is the band containing the molecular lines that have been discovered in the past year or so, and that up to now have been almost entirely an American field. Because of absorption by water vapour in the atmosphere, the dish will have to be on a high dry site—the Americans do some of their observing from Kitt Peak, Arizona. The same constraints hold for the siting of the 60 inch flux collector being built at Imperial College (London), and if the microwave dish ever goes ahead it will be at the same site. At present this looks like being Tenerife.

Now that the scheme for a telescope in Riyadh to be shared by Britain and Saudi Arabia appears to have fallen through, British access to northern skies will hinge on what is being called the Northern Hemisphere Observatory. Funds for this project will not be sought for two or three years. The observatory will have a prime telescope possibly as big as 150 inch with an alt-azimuth mounting, and a second medium-sized telescope. Now that it is accepted that expensive scientific instruments can be built safely outside Britain, site testing in the Mediterranean area has begun. Tenerife is again believed to be in the running.

NEW WORLD

Power, Pollution and Politics

from our New York Correspondent

MAYOR JOHN LINDSAY has now settled for an uneasy compromise, hedged about with all kinds of promises for the future, in the dispute between the City and Consolidated Edison, the utility company supplying metropolitan New York with power. The annual summer power crisis has this year been punctuated by arguments about the application by ConEd to install 1,600 MW of generating capacity at Astoria in Queens, a stretch of industrial wilderness alongside the Triborough Bridge long since abandoned to power stations. Mr Lindsay announced on Saturday last week that he would let the utility company install just half the generating capacity for which it had asked, and enough on the mayor's calculation to assure base-load supplies for the city until 1974. In its agreement with the city, ConEd has also agreed to use natural gas at the new plant if it can obtain supplies, but otherwise low-sulphur petroleum, to push ahead with plans for building nuclear plants, to abandon coal-burning altogether, to import more power by transmission line from outside New York City, to scrub the gases from the new plants and never again to ask for permission for new fossil-fuelled generating capacity. Mr Lindsay may seem to the conservationists to have caved in to ConEd, but if he can hang on he may yet emerge as the man who outlawed fossil fuels from New York.

The long struggle between the environmentalists and ConEd, in which the mayor has sought perhaps unwisely to hold the ring, is not now at an end. There is still dispute about a proposal to build a pumped storage station on the Hudson at a beauty-spot called Storm King Mountain, and although the Federal Power Commission endorsed last week its own earlier decision that the building of that plant could go ahead, there are likely to be several obstacles in ConEd's path before that project can begin. Unlike the Astoria project, Storm King Mountain is intended as a source of power to meet the peak demand for electricity. It was first suggested in the early sixties, but even then evoked protests that the Hudson had been sufficiently despoiled already.

In the battle over the Astoria plant, the environmentalists have been led by Mr Jerome Kretchmer, the Environmental Protection Commissioner for New York. ConEd estimates that by 1974 the peak power need for New York will be more than nine million kilowatts, increasing to nearly ten million by 1975. With 1,600 MW from Astoria it would be able to generate 12.5 million kilowatts by 1974 and another 800,000 by 1975. This would give the city 36 per cent reserve above the projected peak in 1974. ConEd claims that this large reserve is necessary because of the high likelihood of failure in one or more plants. Already this summer two generating plants have failed, reducing capacity by 17 per cent.

Mr Kretchmer and others refused to accept ConEd's arguments, noting that the Federal Power Commission considers reserves of 20 to 25 per cent to be ample. Mr Kretchmer argues that other power

sites are available, but that ConEd does not want to spend the extra money needed to bring the power into the city. He also believes that ConEd could continue to meet any shortages by bringing in power from other utilities, but ConEd responds that other utilities are also facing possible shortages and cannot guarantee any supply to New York beyond 1972.

The chief support for the opposition, however, centres on the dangerous level of air pollution in the city. Astoria is recognized as the most polluted area in the country, and New York itself in recent years has far outdistanced Los Angeles in terms of smog and air pollution. While cars are now considered the major source of air pollution, power plants are not far behind. ConEd claims that the modern plant at Astoria would meet all Federal, state and city health and environment standards; because it also would be replacing older facilities it would in effect decrease the total amount of air pollution in the city. Unfortunately, this will not help the residents of Astoria.

Mr Lindsay's plea that ConEd should use natural gas at Astoria if only supplies can be found is an attempt to reduce the emission of sulphur dioxide and smoke, but there is now such a grave shortage of natural gas that ConEd recently joined with a number of conservation groups in petitioning the Federal Government for a larger supply of natural gas to meet the present needs. In any case, both gas and oil present health hazards. Mr Kretchmer estimates that between 1,000 and 2,000 people die prematurely in New York City each year from sulphur dioxide poisoning; and even if Astoria used low-sulphur oil the plant would add about 15,000 tons of sulphur dioxide to the air annually according to Mr Kretchmer.

Natural gas also has its snags, chiefly that it produces nitrogen oxide, a cause of smog. At a symposium last week sponsored by the Citizens for Clean Air Dr Carl Shy, an epidemiologist at the National Air Pollution Control Administration, estimated that the nitrogen oxide from the Astoria plant would cost society between \$250,000 and \$750,000 a year, the cost of increased respiratory illness among the local residents.

Whatever the truth, the debate has amply demonstrated that power has never been properly planned in the city. The Astoria plant appears to be an inadequate, and probably dangerous, solution to the present crisis, but the philosophy behind it is even more questionable. Until recently it was assumed that the city, like the rest of the country, could continue to expand simply by increasing all inputs. But services in the city have begun to disintegrate in recent years, possibly through poor administration, but certainly through overloading and strain. The problem facing Mayor Lindsay and ConEd should not be how to provide more power, but how to use what is available more efficiently. The way things are going, the need for more power will certainly disappear as more people desert the city for the still somewhat clean air of the suburbs.

AEROSPACE INDUSTRIES

Lockheed Lives Again

THE project for building the huge military transport aircraft called the C5A has survived yet another attack by critics in the Senate of this and other new weapons systems, with the result that the Lockheed Company will not find itself having to abandon manufacture of the aircraft for lack of funds. It remains, however, to be decided how the relationship between the Department of Defense and the luckless company will eventually be resolved. Already there are reports that a part of the price that Lockheed will have to pay for being bailed out of its contract for development and manufacture of the aircraft will be the transfer of the Georgia plant at which the work is concentrated to public ownership.

The C5A has become in the past few months a haunting admonition for all industrial concerns anxious to win military contracts. In technical terms, the aircraft is a remarkable development in its own right—it is designed to lift more than 80 tons of military equipment. Much of the engineering interest of the development has been the design of a wing sufficiently large and efficient to provide the necessary lift. Administratively, the contract for the development work, originally signed in October 1965, broke new ground by being one of the first fixed-price contracts of this size negotiated by the Department of Defense as part of Mr McNamara's belief that it should be possible to save public money by the introduction of commercial procedures into military procurement. The original contract supposed that \$1,900 million would cover the cost of development and the manufacture of 115 aircraft. At the beginning, Lockheed must have been given some assurance that the project would not become a very heavy loss by the provision in the contract allowing for a price increase for the second half of the production run if the estimated costs should have turned out to be too low in the production of the first 57 aircraft. In the event, the complications of the wing design and of the electronic equipment built into the aircraft have plainly turned out to be much greater than originally supposed, while the Pentagon seems to have set its face against a loosening of the tight performance specification originally agreed on. On the present showing, it seems as if the cost of the whole enterprise would turn out to be close on \$5,000 million, although the total cost was for practical purposes reduced last October when the Air Force said that it would settle for 81 aircraft rather than the 115 originally ordered.

This reduction of the scale of the operation seems to have aggravated Lockheed's troubles. Under the original contract, it would have been possible to offset losses on the first half of the production run by increasing the price charged to the Air Force for the second half of the order, although there was an upper limit to the extent to which Lockheed could expect to make good its losses in this way. With the curtailment of the second series of aircraft ordered, the scope for recovery in this way has also been curtailed, and it seems to be agreed that Lockheed will make a loss of somewhere between \$200 million and \$650 million on the whole operation, depending on the outcome of current negotiations with the Department of Defense.

The Lockheed issue came up in Congress last week in the form of an amendment to the Military Appropria-

tions Bill put forward by Senators Proxmire and Schweiker, two redoubtable critics of military expenditure. Their object, on August 20 and then on August 26, was to limit the freedom of the Department of Defense to spend a sum of \$200 million set aside in the C5A appropriation for what are called contingencies. This sum of money is additional to the \$334 million estimated by the Air Force to be due to Lockheed under the terms of the contract in the current financial year, and which is thought sufficient to complete some 42 aircraft. The assumption is that the contingency allowance will in practice be used to make good some of the company's expected losses. The arguments for making these payments, put forward last week in the Senate, turn around the strategic advantages of the C5A and the likelihood that too fierce a view of the situation might force Lockheed to default on its contract or even to file for bankruptcy. In the event, the Senate agreed that the \$200 million should be spent, which gives the Pentagon an opportunity to find a way of keeping production going. From last week's debate, however, it is clear that there are influential voices in the Senate against too lenient a settlement. Whatever happens, there is a feeling that defence contracting will never be the same again.

DEFENCE POLICY

ABM Undeterred

As everybody expected, there was no fight in the Senate when eventually Senator Brookes's attempt to confine the deployment of the Safeguard to the two sites at which deployment has already begun came up for debate. Unlike the Cooper-Hart Amendment to the Military Appropriations Bill (see *Nature*, 227, 770; 1970), the Brookes Amendment would have allowed the Department of Defense to spend all the Safeguard money requested for 1971, but would have compelled the diversion of the \$300 million odd allocated to the preliminary work at the Whiteman base in Missouri to the improvement of the radar defences at the sites in Idaho and North Dakota. Inevitably, the argument turned not so much on the political question of whether the work being carried forward on Safeguard will help or hinder the SALT talks, due to be resumed in Helsinki in November, but on the admitted inadequacy of the radars being put in at the Safeguard bases. During the financial year that has now begun, the Department of Defense intends to equip the two existing sites with extra Sprint missiles, so as to help ensure the defence of individual Minuteman silos, but Dr John Foster, Chief of Research at the Pentagon, agreed earlier this year that a sound defence of these missiles would require point-by-point radars as well. It is entirely understandable that the Senate should seem to be on weaker ground when trying to force new patterns of technical development on the military than when arguing about general principles, but last week's debate nevertheless provided a fresh insight into the ways in which the Safeguard system is being put together from its separate components.

Eventually, there will be twelve missile sites, covering the United States uniformly. At each of the sites will be a local radar system with a range of several hundreds of miles, and at seven of them will be Presimeter Acquisition Radars with ranges of several

thousands of miles. Both radar systems consist of phased arrays of antennae mounted on the exterior walls of concrete bunkers several hundreds of feet in their dimensions above ground. For practical purposes, the long range radars will control the flight of the long-range Spartan missiles, the first of which are to be tested in action (against dummy ICBMs) this summer. The shorter-range radars will control the Sprint missiles, designed for the rapid acceleration necessary if comparatively local interception is to be successful. What seems now to have been established by those critics of the system who say that Safeguard will not function well is that the shorter range radars may be saturated by a sufficiently coordinated enemy attack or by the use of multiple warheads or even dummy warheads. What Senator Brookes was arguing last week was the need to supply this extra equipment so as to make sure that some at least of the Minuteman sites are properly defended. His case was defeated fifty-three to forty-five.

AGRICULTURAL GENETICS

Corn Blight hits Male Sterility

THE corn blight which has already damaged crops in the southern states in the past few weeks has now reached Iowa and other states in the mid-West corn belt, throwing the commodities market into confusion and causing consternation as far away as Washington. Until the growing season is over, some weeks from now, it will be hard to tell whether the yield of corn—maize to many people outside the United States—will be reduced by the five per cent or so which the more cheerful agronomists are talking about, or whether a quarter of the crop will then be found to have disappeared. In Chicago, the commodity markets have already responded by increasing the price of corn by something like 20 per cent. An Australian entomologist, back last week from Iowa, takes the more gloomy view, saying that "they should have seen this coming all along".

The fungus responsible for the blight, *Helminthosporium maydis*, has been known in the southern states for the best part of a century. In the past twenty years, however, its effects have been kept in check by the development of resistant varieties of corn. What may now have gone wrong is that the male-sterile varieties of corn now widely planted in the United States have, by their genetic stability, provided an especially vulnerable target for a recent mutation of the fungus. If reports that the male-sterile varieties are now suffering most severely from the blight should be confirmed in the next few days, the plant breeders who have recently been boasting of the virtues of male-sterile varieties may find themselves pilloried, not praised.

Corn plants are bisexual, with the male reproductive organs carried on tassel-like appendages. In what have become the old days, farmers would attempt to ensure cross-pollination of corn plants by removing the male appendages from alternate rows of corn plants—a costly procedure. With the emergence in the past few years of varieties with improved yield and disease resistance, there was also a natural welcome from the emergence of a strain of corn from the plants of which the male reproductive organs would be discarded before maturity, and this is now the most commonly

planted variety of corn in the United States. For a time, at least, the lack of cross-pollination and the genetic stability which was the natural result seemed to be a great advantage. The same genetic uniformity may now, however, account for the vulnerability of the corn crop in the Middle West and the South. Certainly the fungus, first noticed in its new form only a year ago in Illinois, has spread like wildfire. For the plant breeders, the problem is what to plant next year. Corn farmers may yet find themselves detasselling their plants.

DEMOGRAPHY

Population Explosion Falls Flat

THE falling trend of the birth rate during the sixties has now prompted the Census Bureau of the Department of Commerce to publish new estimates of the population of the United States in the decades ahead. On present trends, the population in the year 2000 is estimated to be 281 million, or a little less than the lower bound for the year 2000 put out as recently as 1967 by the Census Bureau. These substantial fluctuations of the official estimates are not so much a sign of poor arithmetic at the Census Bureau but of the inherent difficulty of estimating the fertility rate of women, both as the gross figure for the average number of children per woman in the population and as a function of the age of the child-bearing population.

As in the past, the Census Bureau has carried out forward projections for each of several assumptions about the fertility rate for women ranging from 3.35 children per woman (for women not yet of child-bearing age) to 2.45 children per woman. The fertility of American women in the sixties appears to be close to the lower of these limits. The new projects also include a forward projection based on the assumption that the completed fertility rate of American women works out at 2.11 children per woman, the ratio necessary to maintain the population at a constant level (which would amount to a population of 276 million in the year 2035 and thereafter). Each of the assumptions about gross fertility rate is accompanied by a different set of assumptions about the timing of births and for practical purposes it is assumed that decreased fertility is accompanied by later child-bearing. The unexpected character of the present low fertility in the United States is confirmed by the way in which it has been necessary for the Census Bureau to go back to the Great Depression for information about the timing of births in periods of low fertility, a somewhat hazardous procedure. It has also been necessary to make assumptions about the rate of immigration, and the Census Bureau has settled either for a conservative 400,000 souls a year or, in its attempt to estimate the pattern of a stable population, for none at all.

With these assumptions, the upper and lower bounds of the population twenty years from now are put at 277 million and 255 million respectively, compared with the 203 million now estimated for the population of the United States. If the fertility of the population should however fall merely to the replacement level and if immigration is brought to a halt, the population of the United States in 1990 will be 248 million—a comparatively small reduction from the lower bound corresponding to the present level of fertility. The

forward projections now published consist not merely of total population as a function of time but of the age distributions corresponding to each set of assumptions, and it is no surprise that the least quickly growing or even static populations are characterized by smaller proportions of younger people.

Although the new calculations are no doubt a valuable correction to the estimates published three years ago, outsiders may well ask whether enough is yet known about the causes of the decline in fertility in the sixties for any forward projections to be meaningful at this stage. In the sixties, the crude birth rate (births per year per 1000 population) fell from 23.9 in 1960 to 17.6 in 1968, and there is as yet no sign that it will be halted. Even the most pessimistic of the forward projections, however, implies that there will be an increase of the crude birth rate in the seventies and early eighties. On present form, there is very little sign of such a tendency. At the same time, however, it is only natural to ask whether the recent rapid decline of the birth rate represents a reduction of the fertility of women or, alternatively, a drastic change of child-bearing pattern such as might be constituted, for example, by a postponement of child-bearing to a later age. Even the results of the 1970 census, now being analysed, are unlikely to throw much light on these and other possibilities; from which it follows that the embattled Census Bureau is likely to find itself putting out yet another correction of its forward estimates before many years have gone.

METEOROLOGY

Explosions make it Rain

EARLIER this year the United States celebrated the hundredth anniversary of the American Weather Service, set up largely as a result of prodding by Professor Increase A. Lapham of Milwaukee after storms on the Great Lakes in 1868 and 1869, during which more than five hundred seafarers lost their lives. Now, in 1970, the American Weather Service must be the best equipped in the world. For an outlay of about five hundred dollars anyone can build the equipment to pick up photographs from the automatic transmission cameras on American meteorological satellites. Forty-five national weather services are known to be taking these pictures. Satellites are being launched into geostationary orbits so that, fixed at one point above the equator, they can follow storms as they develop. Cloud cover can now be measured over the night-time half of the Earth using infrared sensors. As much as anything, the satellites mean that data can now be recorded over regions that are otherwise virtually inaccessible except at great expense—most of the oceanic areas of the southern hemisphere, for example. Because of the satellites the US Navy no longer has to station weather ships along the air routes from New Zealand to the bases in Antarctica.

A celebratory history of the Weather Bureau has now been published (*A Century of Weather Service*, by Patrick Hughes; Gordon and Breach, 1970). As much as anything the book is fascinating for its illustrations, photographs of the pioneers of meteorology in the United States and their equipment. But the history of meteorology has not been entirely a success. Efforts to modify the climate artificially have had equivocal success. The emphasis has been on

inducing rain, whereas in the Soviet Union, the other major centre of this kind of experiment, comparable effort seems to have been spent on making the weather as pleasant as possible. In the United States there have been a variety of experiments since 1945, but as long ago as 1890 Congress appropriated money to General R. G. Dyrenforth to find out whether explosions cause rain. A series of unsuccessful tests in 1891 and 1892 using batteries of cannons, and bombs with time-fuses, carried by balloons and kites, culminated in the firing of balloon bombs at forty-five minute intervals from noon until 3 a.m. the following day, after which it indeed began to rain on the sleepless inhabitants of San Antonio.

SPACE BUSINESS

Disputes about Satellites

THE National Aeronautics and Space Administration seems to be going through a bad patch in its attempts to award contracts for the development of specific Earth satellites. Earlier this year, the award of a contract to the General Electric Company for the development of a Technological Satellite was challenged and eventually cancelled (see *Nature*, **226**, 402; 1970) on the grounds that the company had an unfair advantage over its competitor, the Fairchild-Hiller Corporation. Now it appears that a similar complaint against the award of a contract to General Electric for the development of an Earth Resources Satellite has again been made by the unsuccessful bidder, TRW Inc.

The dispute on this occasion seems to centre on the degree to which the two companies were given access to a preliminary study of the design of the system carried out by the Bendix Corporation. It seems to be agreed that both the bidders in the competition were sent copies of this report only a few days before their proposals were due at NASA, but that the General Electric Company worked with the Bendix Corporation on the preparation of its own proposals. On this occasion, it appears that NASA is satisfied that there is no need of a formal reappraisal of the award of the contract.

Foreign Visitors

THERE is some consternation at Stanford University about the decision of the Czechoslovak Academy of Science that Dr Jiri Masek, head of the department of inorganic chemistry at the Polarography Institute at Prague, should not be allowed to take up a National Science Fellowship at Stanford. According to a statement by the university last week, Dr Masek has been informed that the academy considers that the numbers of Czech scientists working abroad now exceeds "a reasonable limit", and that until some of those working abroad return home, others will not be allowed to leave. Dr Masek has been told, according to Stanford University, that he should keep on applying for permission to work at Stanford. Professor Henry Taube at Stanford, with whom Dr Masek would have worked, says that he is prepared to wait for him.

Some Pathologies of the Scientific Life

(Extracts from the Presidential Address by J. M. Ziman to Section X of the British Association Meeting)

A COLLECTION of pathological cases must inevitably seem like an attack on the whole body of science. In the present irrational mood of our intelligentsia, it would seem folly to add more fuel to the fires on which they are mentally roasting us—with our books piled high about us and our instruments stuffed down our gullets. Let me say, then, most emphatically, that I do *not* believe that the internal state of the scientific community is desperately unhealthy.

One of the characteristics of modern science that many people find scandalous is the political in-fighting that breaks out when big administrative decisions are to be taken, and big money is to be handed out. We rightly expect distinguished scientists to be honest, disinterested, courteous, etc., in the laboratory or lecture hall—just as we expect doctors to be humane and painstaking in the consulting room or operating theatre. But the general administration of a large scale organization, whether a scientific research establishment or a hospital, is not in itself a scientific or medical activity, and demands an entirely different code of behaviour. It would be pathological if this aspect of the scientific community were *not* subject to the general sociological laws of bureaucratic and political systems.

I want to discuss those occasions when the *internal* social and psychological mechanisms of scientific research break down. Science is a communal activity, directed towards the creation of a rational intellectual consensus. Scientists are in tacit cooperation when they communicate their results to one another, criticize, recognize, refer to, appoint or promote each other. They act in the expectation that their contemporaries will behave according to certain conventions. Any serious breach of these conventions is a pathological symptom, deserving our attention.

The typical psychopathology of ordinary society is crime. Strangely enough, deliberate, conscious, fraud is extremely rare in the world of academic science. One would have thought that the material rewards of research were tempting enough—cosy university appointments, research grants galore, plenty of conspicuous travel—to encourage a noticeable amount of scholarly dishonesty. Yet the only well-known case is "Piltdown Man", which is more of a monument to the absolute trust that we have in a reputable fellow scientist than an example of a grandly conceived crime. I suppose there must be a fair bit of lazy cheating—experimental data filled in by Guess and by God, or theories stolen from little known works and plagiarized—but I have never come across it myself.

One must not get the idea that scientists are all that admirable in everyday life. As I have already remarked, they will intrigue for political ends like any Jesuit, and can be as lordly as any consultant physician in the control of their juniors. They can deceive their wives, fiddle their tax returns, drive drunkenly, live beyond their means, feed parking meters, beat their children, and otherwise behave as antisocially as anyone else when the occasion demands. There are scoundrels amongst scientists, just as there

are amongst lawyers, or architects, or naval officers. But I have a very strong impression that these traits are repressed within research itself.

Perhaps the rewards are too meagre, and the risks of being found out are too great. It may be, also, that the long training of the professional scientist conditions him against conscious deceit. Those years leading up to the PhD, the struggle to obtain useful results, to master the theory, to write it all down, and to please his supervisor, are a tough discipline. If he has studied in a good institution, then he will have internalized very high standards of honesty, scepticism, and criticism, so that he will never find it easy to let his mind slide over the difficulties and objections, and thus to rationalize a really crude deception. He should have learnt also how completely each scientist relies upon the sincerity and good faith of those whose results he quotes as evidence for his own conclusions. Unwitting error causes trouble enough: the suspicion that any paper we refer to might be fraudulent would completely paralyse further research. A fierce and uncompromising honesty is one of the standard attributes of the so-called "scientific attitude". I do not think it is inborn, but it is certainly moulded into one by powerful social pressures in the graduate student phase of one's career.

Self-deception, on the other hand, is an exceedingly common phenomenon in the scientific world. We are all, of course, familiar with extreme cults, such as Flying Saucers and Extra-Sensory Perception, on the fringes of genuine science; it is important to realize that the reputable scientific literature abounds with similar, if less obviously fantastic, irrationalities.

What does this type of pathology signify for the scientific life and the scientific community? It is not surprising, perhaps, that the initial claim to some extraordinary discovery should get published. It is the duty of every journal editor and referee to have an open mind towards completely new effects, and to suspend his scepticism temporarily in order to entertain the possibility that some highly speculative and incomprehensible theory may, after all, be correct. But how are we to explain the very large number of papers that often then appear, both in support and refutation of some such preposterous proposal? The truth is, perhaps, that scientific progress is difficult and uncertain. The hope of participating in an important scientific revolution encourages many able professionals to follow up the initial claim. A considerable amount of experiment to establish negative results is then required to debunk the effect or theory. The journals must be kept open to such communications for a year or two, and cannot easily refuse to publish the work of the master and his remaining disciples, who can give respectability to their papers by referring back to the earlier published literature.

The conflict of ideas, results, claims and theories is basic to scientific progress, but there are powerful norms forbidding intense dispute, personal abuse, alienation and fragmentation into mutually irreconcilable "schools". If knowledge is to be "consensible" then division into groups that do not share common

aims, and do not speak or listen to one another, is the negation of science, and must be avoided at all costs. Controversy of this violence, which does occasionally occur, must be regarded as deeply pathological.

The psychological balance of scientific innovators is exceedingly delicate. One must have sufficient confidence in one's own notions to carry conviction in argument. Yet one must not become so deeply committed that one cannot escape from them if they prove untenable. *The Double Helix* brings out the passion and anguish with which scientific research is really pursued. Kubie remarks that "the structure of science adds layer on layer, each burdened by more subtle and complex unconscious emotional investments, demanding of the scientist an ever greater clarity about the role of his own unconscious processes in his conscious theories and experiments, and each requiring an ever more rigorous correction for the influence of unconscious preconceptions". I would add that the "norm" demanding impersonality of expression—for example, the use of a neutral tone and passive voice in scientific writing—is more than a rule for protecting the scientific community from violent disputes; it is a device for warning us of the personal psychological danger of allowing our private passions to take control of us in public.

Intellectual property is, after all, so intangible and evanescent. An original theory or discovery that is acclaimed today may turn out tomorrow to be an error or a blind alley. The question of ownership is much more uncertain than with patents or copyrights; absolute priority of discovery is meaningless within a slowly evolving complex of ideas; yet a single sentence might be enough to convey the essence of a great revolution of thought. Even the most successful scholar is aware of the danger of losing all the intellectual capital that he has so laboriously amassed. An attack upon his point of view threatens his whole reputation and self-esteem: he sees his name in the history books being erased from the column of heroes, and put in a footnote amongst those tiresome fools who have wasted the time of their contemporaries with their errors and irrelevancies.

The pathological phenomena to which I would draw attention are the contrived, and yet almost fortuitous, titles of eminence within the very top ranks of the scientific community. A few hundred Nobel Laureates are not enough to go round amongst the several thousand living scientists who are, one would say, in that class of ability. The same applies to membership of the National Academies—even to our own dear old Royal Society—which have not expanded in numbers to match the growth of the scientific community. Election becomes more difficult—and the disappointment of reasonable expectations is that much more bitter. I fully appreciate the difficulty of any public discussion of this sort of thing, but I think we must admit that it is unhealthy when we can point to a number of first class scientists, still in the prime of their powers, whom every one agrees to be fully of the supposed standard, and who are yet unlikely now to be elected. The function of the Royal Society, and of similar Academies, is to be a meeting place and organ of opinion for *all* the most responsible and senior scientists in the country, and not just a prestigious labelling machine for those who have been fortunate enough to get their noses slightly ahead at the right moment in the race.

Am I insisting, puritanically, that the scientist should lead a lean and austere life? What I mean is not that we should all live like hermits, but that great affluence should not come too easily. It is difficult to point to specific and scandalous failures—yet one must be aware of a certain flabbiness in the intellectual world due to the enormous subsidies it has had to digest. In recent years, it has become just a bit too easy to get a PhD of sorts, and an academic job of sorts, and a grant for research of sorts—to produce yet more PhDs of the same sort. Scientific research is not simply a professional job, to be entered into in the spirit of plumbing or accountancy. Nor is it a mechanical activity, like programming a computer, that can be learnt from a manual. It demands a sense of vocation and dedication; it is an art form, transmitted from master to apprentice by oral tradition and imitation over a period of years. To expand the scientific labour force more quickly than it can be adequately trained must surely lower the quality of the product. The current shake-out in the PhD job market is not, to my mind a symptom of some serious disease, but rather an occasion for a nature cure by gentledieting.

The fact is that the academic community, despite its tendency to look inward and not care much about what the world is doing, is quite easily bought and sold. Dons may not be very ready to undertake the dirty work of Industry and Defence, but they are quite willing to be subsidized to any extent, in the name of basic research, etc., by those whom they despise.

My other example of a pathological—indeed totally destructive—effect of social pressure on organized science comes from the political pole—from the Soviet Union. I refer, of course, to the tragic phenomenon of Lysenkoism. We must all be grateful to Dr Zhores Medvedev for writing, and allowing to be translated and published abroad, his vivid and authentic history of this terrifying aberration in a country supposedly dedicated to rational scientific materialism. The terrifying feature was the apparent normality of the scientific organization within which this false doctrine existed. The tragedy lies not with those few who were forced, by irresistible threats of violence, to keep silent or to say the opposite of their thoughts: it is with the many who seem to have accepted the doctrine as it was taught to them and failed to subject it to their own tests of rationality. We cannot blame a half-educated crank for believing his own theories and trying to get them accepted: we must ask what was wrong with a whole scientific community that it allowed itself to be captured by such crazy notions.

It is easy enough for us to say that it could not happen here. We should, indeed, be singularly unfortunate to have full-blooded Stalinism wished upon us. I hope that at least a few of our own scholars would then behave as heroically as some of the Russian geneticists in those terrible years. But I think we can learn, from this as from the other pathologies I have discussed, some positive facts about the scientific community and the way it really works. In our own democratic and liberal social environment, we take for granted such elementary features as freedom of speech, freedom to travel, permanent tenure of academic office, an independent diversity of universities and other institutions, which are the real guarantees of healthy, productive science.

NEWS AND VIEWS

Après Temin, le Déluge

It is a measure of the excitement invoked amongst molecular biologists by Temin's discovery that RNA tumour viruses can act as templates for the synthesis of DNA (see *Nature*, **226**, 1198; 1970) that no less than ten pages of this issue of *Nature* are filled with reports about the mode of action of these viruses. In the brief time that has elapsed since Temin announced in June that RNA tumour viruses contain an enzyme activity which requires RNA and all four nucleoside triphosphates to synthesize DNA, a flood of research workers have cast covetous eyes on the pickings to be gleaned from Teminism (see *Nature*, **227**, 887; 1970).

The immediate product of the RNA-dependent DNA polymerase enzyme activity found by Temin seems to be a double-stranded hybrid nucleic acid, the result of synthesis of a complementary strand of DNA on part of the viral RNA template. In an impressive burst of activity, Spiegelman and his colleagues at Columbia University have characterized this hybrid, and have shown by hybridization studies that the DNA strand is indeed complementary to the viral RNA (*Nature*, **227**, 563; 1970). On page 1026 of this issue of *Nature*, Green and his colleagues at St Louis University observe that the buoyant density of the RNA-DNA hybrid synthesized *in vitro* is close to that of the viral RNA itself; this implies that only a rather small part of the RNA genome is taking part in the synthesis of complementary DNA. It seems likely that rather more of the viral RNA directs DNA synthesis *in vitro*.

What is the purpose of this unusual information reversal? Evidence is now mounting to support the view that formation of the RNA-DNA hybrid is just a first step in the synthesis of a double-stranded DNA carrying the genetic information of at least some of the genes of the RNA tumour virus. Such a DNA would be able to integrate into the genome of its host cell (it is tempting to draw an analogy with the integration of bacteriophages into bacterial chromosomes); this integration would explain how RNA tumour viruses can stably transform their hosts. It seems unlikely that the RNA-DNA hybrid itself could fulfil this function, and on page 1029 Spiegelman *et al.* report the discovery of a second DNA polymerase activity in the virion which is probably concerned with the production of duplex DNA.

This enzyme, at least, is conventional in its mode of action and uses DNA as template for the synthesis of further DNA. It replicates double-stranded DNA well but works less efficiently with single-stranded DNA templates. Because all the DNA-dependent DNA polymerases found previously prefer single-stranded templates, this enzyme is interesting in its own right,

as well as for the part which it must play in viral infection. This may be the reproduction of the duplex DNA carrying viral information to increase the chances of a successful integration into the host cell chromosome.

But where does the double-stranded DNA template come from for this enzyme to act on? Presumably, the virion must contain yet another enzyme activity to convert the RNA-DNA hybrid to a duplex DNA. This might be the synthesis of a new DNA strand to displace the RNA strand. It seems likely that this activity is not vested in a third enzyme, but is another function of the DNA-dependent DNA polymerase, for Spiegelman has found (see *Nature*, **227**, 887; 1970) that poly dC · poly rG is a remarkably good template for this enzyme.

Demolition of the hallowed idea of the molecular biologist that RNA cannot synthesize DNA has prompted a reinvestigation of other ideas. It has been claimed for some time that RNA tumour viruses do not contain any DNA, but Levinson *et al.* (page 1023) and Green and his colleagues (page 1026) have taken another look at this question, and find that there is a small amount of DNA in the virion. Levinson *et al.* find that it comprises two components, one which cosediments with the RNA viral genome at 65S, the other being a small unit sedimenting at about 4S. The DNA made *in vitro* by their preparation of viral DNA polymerase sediments very similarly, but it is not yet clear whether this is a coincidence or whether this DNA has been synthesized by the viral enzyme for some purpose.

The existence of biochemical mechanisms which synthesize duplex DNA from the viral RNA suggests that this process must play some part in the action of these tumour viruses; but what direct evidence is there that viral gene functions are really needed for transformation? On page 1021, Martin reports the isolation of a temperature sensitive mutation in a function of the Rous sarcoma virus which is needed for transformation of the host cell. The mutant strain is normal at 36° C, but although it grows normally when the temperature is increased to 41° C, the infected cells retain their characteristic morphology; they are not transformed. So the mutant function must be concerned with host cell transformation, but is not needed for the growth of the virus. Even more significant, when cells which had been transformed at the lower temperature were increased to 41° C, they gradually reverted to the appearance characteristic of normal cells. This implies that the continued expression of viral genes is needed if the host cell is to be maintained in a transformed state. And this is most simply explained if those genes are integrated into the genome of the host.

PROTEIN SYNTHESIS

Translation not Universal

from a Correspondent

NEW information is still being obtained about various aspects of the translation process, during which genetic information carried on messenger RNAs is used in the biosynthesis of specific protein molecules. It is becoming increasingly clear that in spite of the universal nature of the genetic code, different parts of the translation apparatus are not entirely interchangeable between different organisms. In the past, various workers have synthesized the globin portion of rabbit haemoglobin *in vitro*, using with gay abandon unwashed ribosomes from rabbit reticulocytes (carrying the messenger RNAs for the globin chains and the factors necessary for protein synthesis) together with aminoacyl tRNAs from *Escherichia coli* or yeast. Because the primary structures of the globin chains are known and the system has several technical advantages, it has proved particularly useful for exploring the degeneracy of the genetic code.

But, in a careful study, Hunter and Jackson (*Europ. J. Biochem.*, **15**, 381; 1970) have re-examined the products actually obtained when globin is synthesized in this way, and sadly conclude that substantial levels of miscoding occur during translation in this heterologous system. They demonstrated this by using tRNA charged with radioactive amino-acids, astutely choosing three amino-acids (cysteine, methionine and valine) which occur rather rarely in the globin molecule, so as to be able to study where these were incorporated within the protein. They mixed the radioactive globin which was synthesized with carrier amounts of natural rabbit globin, and fingerprinted tryptic digests of the mixtures. The fingerprints were stained with ninhydrin to reveal the peptides arising from the carrier material and then autographed to find out which peptides contained the radioactive amino-acids.

In all cases, they found that substantial amounts of the labelled amino-acids occurred in peptides not normally expected to contain them. In some instances peptides with altered mobilities were produced by the amino-acid changes. In a few surprising cases they found that peptides which ought to have contained labelled amino-acids did not, and they were unable to explain this entirely satisfactorily although they wondered if some residual reticulocyte tRNAs from the unwashed ribosomes were competing very effectively for these sites. A judicious control experiment demonstrated that, under identical conditions, incorporation from reticulocyte valine tRNA was found only in the true globin peptides. From their results they were able to deduce that the cysteine tRNA (which normally recognizes UG_C^U) was also probably reading the arginine codons CG_C^U because of mismatching of the codon-anticodon complex. Hence in five cases cysteine was introduced in place of arginine. They also suggested that both the methionine tRNA_F and tRNA_M were extensively reading GUG, and that methionine was being introduced instead of valine into various points in the molecule. Hunter and Jackson believe that the most probable explanation of these somewhat traumatic results is that the reticulocyte ribosomes are unable to position all the *E. coli* tRNA species correctly relative to the codons on the

mRNAs, presumably because of nucleotide sequence differences between the tRNAs from *E. coli* and reticulocytes.

Some important results from the wonderful world of factors are reported by Revel and his colleagues in two recent papers (*FÉBS Lett.*, **9**, 213 and 218; 1970). The attachment of mRNAs to ribosomes in *E. coli* is known to depend on the presence of three protein factors A(F1), B(F3) and C(F2). Factor B is necessary for the recognition of natural mRNA templates, as opposed to synthetic polynucleotides. They find that factor B is heterogeneous, and can be split into multiple components by chromatography on columns of DEAE-cellulose and hydroxylapatite. These fractions are distinguished from each other by preferentially stimulating the translation of different mRNAs *in vitro*. Thus one of the fractions stimulates the translation of bacteriophage MS2 RNA, while the other activates the translation of bacteriophage T4 mRNA (assayed by the product of translation of the lysozyme cistron). The two activities were not entirely separated from each other, and it is unclear whether this is because of incomplete purification, or whether each really possesses some activity in the other system. The fraction stimulating the translation of MS2 RNA could be further split into at least three peaks. They elegantly demonstrated that one of these peaks caused preferential translation of the coat protein cistron. Further evidence as to the regulatory role of the B factor fractions was obtained by studying cells infected with bacteriophage T4. After infection, the stimulatory activity of factor B for the translation of T4 mRNA, and particularly the late messenger, was considerably increased, while factor B activity in MS2 translation was diminished. These findings suggest that a further mechanism governing the control of gene expression is operating at the translational level. It will be important news indeed if analogous systems are characterized in eukaryotic cells.

PROTEIN SYNTHESIS

Jumping on the Bandwagon

from a Special Correspondent

If the meeting on mammalian protein synthesis held at Cold Spring Harbor last week had been held six months ago, almost all of the thirty-three contributions would have been dramatic news. But research has progressed so fast that by now, however, the topics discussed seem hackneyed and weary; as repetitive report succeeded report, it seemed at times that the predominant view of participants was that the only problem worth solving in molecular biology is how haemoglobin synthesis is initiated in reticulocytes.

Haemoglobin turns out to be initiated in a way very similar to bacterial proteins; as D. Wilson (Cornell University), R. J. Jackson and A. R. Hunter (University of Cambridge), A. Yoshida (University of Washington) and H. F. Lodish *et al.* (MIT) showed, a special initiator tRNA (tRNA_i^{met}) provides a methionine residue to start the globin chain. This methionine is cleaved from the protein when the growing chain is about twenty amino-acids long, perhaps because it is then no longer protected by the ribosomes and

becomes available to an aminopeptidase (although this enzyme has not yet been identified). The only difference from bacterial protein synthesis is that the methionine does not have its free amino group blocked by a formyl group.

Mammalian systems for protein synthesis *in vitro* still remain rather unsatisfactory when compared with the more sophisticated systems that can be obtained from bacteria. One difficulty with reticulocytes, for example, is that endogenous mRNA cannot be washed off the ribosomes. It is perhaps a tribute to faith that the mechanisms of protein synthesis are universal that so many reports (and in particular those from MIT) announced the establishment of heterologous systems, in which the various parts of the protein synthetic apparatus are derived from different organisms. This usually means that *E. coli* ribosomes and/or tRNAs are used to translate an alien messenger. Haemoglobin mRNA and the mRNAs of animal viruses are popular templates to use in such systems, although they are rarely translated with the fidelity that prevails *in vivo* (see page 999 of this issue of *Nature*). For example, D. M. Reksoh *et al.* (MIT) have found that poliovirus RNA can be translated into virus specific products by *E. coli* extracts, but initiation takes place at between eight and fourteen sites.

This contrasts with the bizarre translation of poliovirus RNA *in vivo* into one large protein which is only subsequently cleaved into individual protein entities. But more encouraging results have been obtained in translating poliovirus and encephalomyocarditis (EMC) RNA (a related virus) *in vitro* with systems derived from their physiological host cells. J. V. Maizel *et al.* (Albert Einstein College of Medicine) have been able to isolate polysomes from poliovirus infected HeLa cells; this makes a major protein product about the size expected to correspond to the whole genome. A. E. Smith (MRC, Cambridge) reported that EMC RNA can be translated *in vitro* by a system derived from uninfected Krebs IIA cells, and has identified one of the sites where the EMC protein is cleaved.

Noticeably fewer faces were present when the meeting ended, but those whose minds had clotted earlier in the proceedings missed the first announcement of the finding of termination factors in mammalian systems. J. L. Goldstein, A. L. Beaudet and C. T. Caskey (NIH) have obtained a protein preparation, admittedly crude at present, which assists termination on reticulocyte ribosomes. In both bacterial and mammalian systems, fMet-tRNA_f is "sticky"; it binds non-enzymatically but securely to ribosomes. Goldstein *et al.* have taken advantage of this to prepare an assay for termination; the appropriate codons or messengers can be added to fMet-tRNA_f bound ribosomes and release of formyl methionine is measured. This shows that there is a factor which responds to the codon UAA in reticulocytes, and the NIH workers suspect that their preparation also contains a stimulatory factor which assists its action (a similar mechanism prevails in bacteria). No release factor responding to the other nonsense codons, UAG and UGA, has been identified yet.

Another interesting result of this work is that it has proved impossible to differentiate the action of peptidyl transferase (the ribosomal enzyme which synthesizes peptide bonds) from the release activity.

Although these two activities are inhibited by a different spectrum of antibiotics according to whether bacterial or reticulocyte ribosomes are used, in each case, any particular antibiotic inhibits either both activities or neither. This supports the idea (see *Nature*, 227, 337; 1970) that peptidyl transferase plays some part in the termination of protein synthesis.

PARASITIC FISH

Suckers and Pickers

from our Marine Vertebrate Correspondent

THE very specialized fishes known as remoras, shark suckers, or diskfishes (in the United States) have for long attracted the attention of man. Their habit of attaching themselves by the powerful sucker on the back of the head to larger fishes, especially such fearsome creatures as sharks, turtles, and even ships, always merited a passage in the earliest zoology. They made their mark on history, too, for Pliny recounts that Mark Antony lost the naval battle of Actium because at the critical moment his ship was held back by a remora. For all this long-standing interest in the habits of these fish their life history and biology has been relatively unknown. For this reason, the publication by Roger F. Cressey and Ernest A. Lachner of a paper on their diet and life history (*Copeia*, 1970, 310; 1970) is of considerable interest.

Eight species of these marine fishes are now recognized, of which specimens of six were examined in Cressey and Lachner's study. Several interesting features emerge from their data and from the literature. First, several of the more morphologically specialized species are strongly host specific. One species, *Remora australis*, has only been found attached to whales and dolphins; another, *R. osteochir*, is almost always found on swordfish and their allies; while *Remorina albescentis* is usually found in the mouth or gill cavity of the giant tropical devil fishes or mantas.

The association between remora and host may not be so casual as had for a long time been thought, for it has often been claimed that the association was ephemeral. But Cressey and Lachner suggest that a single host may be the life abode for the remora, and they report finding entire "families" consisting of small juveniles, subadults, ripe males and gravid females on the same host. Although conclusive evidence is lacking, the authors feel that it is likely that mating or other reproductive behaviour takes place while the remoras are attached to the host. The very earliest young stages are, however, known to be free swimming. An indication that supports their suggestion that the association is more permanent than had been thought previously lies in the relative swimming abilities of the hosts and the species of remora. Observations on living fish show that they cannot match the speed or endurance of most of the host species (which include some of the most powerful swimmers known). For this reason alone it seems unlikely that the remora would frequently completely detach itself, for once out of touch it would probably not catch up again!

Cressey and Lachner's primary contribution to knowledge of these fish, however, lies in their detailed confirmation that remoras act as cleaners to their hosts, often feeding primarily on the external parasites of the body and branchial regions. This had first been

suggested by two Argentinian ichthyologists, Szidat and Nani, as long ago as 1951, and later observations by other workers tended to confirm their suggestion. These observations were, however, based on very few fish examined, but the present study of the stomach contents of 401 individuals shows that the habit is widespread in the group. In only one of the six species investigated was the evidence inconclusive. The role of parasite-picker varies with the species involved: the commonest species, *Remora remora*, is an active cleaner, and the mutualistic relationship between fish and host is strong, but the mutualism is less strong in other species. Parasite-picking varies with the size of the individual although not consistently through the group—some are more active when young than when adult, some adopt the habit with maturity, while *Echeneis naucrates* is active as a cleaner in middle age.

BEES

Queens and their Consorts

from a Correspondent

A QUEEN honeybee lays fertilized eggs in worker cells in the bee comb but unfertilized eggs in the slightly larger drone cells. How does she differentiate between them? At the fifth conference of the Bee Research Association held at Grantley Hall in Yorkshire from August 21 to 23, Dr N. Koeniger (Bee Research Institute, University of Frankfurt) reported noticing that when the queen inspects a cell before laying in it, she inserts not only her head into the cell, but also her front legs. By attaching "spurs" of sellotape to a queen's forelegs, Dr Koeniger made it impossible for her to get these legs into a cell during inspection. All the eggs the queen then laid were fertilized, whatever the type of cell, but when the sellotape "spurs" were removed, the normal pattern of laying was resumed. These experiments and others, in which various parts of the forelegs were amputated, show that the queen uses her forelegs in some way to differentiate between the two types of cell, but the mechanism remains a mystery.

Worker bees—infertile female members of the colony—carry out most of the household duties in the hive, such as comb building, food gathering, cleaning of the hive, feeding the queen and the developing brood, and so on. They also seem to control the queen's egg laying to a large extent according to Dr Delia Seager (University of Aberdeen). Dr Seager described how, when a colony is preparing to swarm, egg laying is reduced and the "retinue" of workers stops feeding and grooming the queen. Instead, the workers shake the queen constantly and quite violently, sometimes several hundred times in an hour. The result of all this treatment is that the queen is slim and muscular enough to swarm.

With the distinction between unfertilized and fertilized eggs being so important in the social structure of the bee colony, attention is now turning to the largely unknown mechanism of fertilization. Dr G. Koeniger (Bee Research Institute, University of Frankfurt) described a new technique which throws some light on the process. After two years' experiments she has perfected a method which involves making an incision in an abdominal tergite of the queen (avoiding the flexible intersegmental membrane), lifting a small

flap to give access to the internal organs and replacing the flap, all within 10 to 15 minutes. The queen immediately licks the wound, which heals, and she seems to live a normal life in the colony for several weeks. Using this method, Dr Koeniger has succeeded in removing the spermathecal gland from living queens, who, after the operation, return to their colonies and resume egg laying. When both branches of the gland are removed, only unfertilized (drone) eggs are laid afterwards. In contrast, when only one branch is removed, the queen lays worker and drone eggs normally in the appropriate cells, indicating that the operation itself does not cause the change. It seems therefore that the spermathecal gland must be involved in releasing from the spermathecae the spermatozoa which fertilize the female (worker) eggs.

PLANETS

Primaevial Surface of Mars

by our Astronomy Correspondent

THE latest chart of Mars, published in August by the US Army Topographic Command, is something of a disappointment. For the most part it looks like charts of Mars always have done—a shadowy patchwork of light and dark areas with science fiction names like Panchaia, Memnonia and Xanthe. Two patches showing greater detail in the shape of fuzzily drawn craters hardly do justice to the original Mariner photographs.

It is now more than a year since the close approach of Mariners 6 and 7 to Mars. As with the early Moon probes, the Mariners have revealed some fascinating new features on the surface of Mars but have failed to answer the basic questions that are in everyone's minds. Coinciding with the publication of the new Mars chart, Commission 16 of the IAU dealing with planets and satellites met last week to review the new data.

Electronic processing of the more than two hundred television pictures has provided full-time work for about a dozen people. Electronic noise has been removed from the pictures, they have been corrected for geometric distortion, and enhanced versions to bring out the faint features have been produced in the computers at Caltech.

Even the depth of the icecaps, at one time thought to be a sprinkling of carbon dioxide snow, is now in question. Near-encounter pictures of the south polar region show what are being called "etch pits" apparently tens of metres deep that seem to be in the snow rather than the underlying topography. If the snow is as deep as this, it is hard to see how all of it can be removed during the seasonal cycle. So the Mars mission in 1971 will be on the lookout for quasi-permanent drifts of snow that have escaped attention, possibly because of a covering of dirt.

More than anything else, the surface of Mars seems to resemble a worn-down version of the lunar highlands. The highlands-maria dichotomy is absent, however, and the line being taken by the Mariner Television Experiment Team is that what is being seen is the basic accretion surface. But there are two areas which suggest that internal processes may be beginning on Mars. One is a featureless area in Hellas with no craters down to the 300 metre resolution limit, indicating that only a comparatively short period of time is

taken by the process that wipes the surface clean. The second possible signature of underground processes is a patch of what is termed "chaotic terrain", an almost craterless area made up of short ridges and depressions typically 1 to 3 km wide and 2 to 20 km long.

More has been learned about the atmosphere, however. The television experiment detected a multilayer structure at the limb, from about 10 km up to 50 km, which the infrared spectrometer experiment indicates may be solid carbon dioxide. Dr G. Pimentel reported that there is also infrared evidence for silicate dust in the atmosphere, and a "quite low" abundance of H_2O may have been detected. New upper limits are being placed on the extent of NO , N_2O , OCS , CH_4 , O_3 and NH_3 . As expected, the ultraviolet spectrometer shows a spectrum similar to the laboratory spectrum of carbon dioxide irradiated by sunlight, but what is odd is the scarcity of atomic oxygen. Carbon dioxide in the laboratory is easily broken down by sunlight. A broad absorption band at 2500 Å interpreted as ozone is detected over the pole caps, but not over the unfrosted areas. Either the pole caps are acting as a cold trap, or for some reason the band is easier to see against a light background. The ultraviolet has also shown that aerosols of sizes less than a tenth of a micron or so are present in large quantities, scattering twice as much light as the atmosphere itself.

It is pleasing that the different methods of drawing the elevation profile of the Martian surface—by radar from the Earth, and by measuring the depth of atmosphere at different points from the intensity of spectral lines—are more or less in agreement in areas where they have all been tried. But the elevation differences that have been measured, possibly as much as 15 km between highest and lowest points, are comparable with the interval between the deepest ocean and the highest mountains on Earth and raise the question whether isostasy is also at work on Mars.

PALAEOMAGNETISM

No Correlations in the Canaries

from our Geomagnetism Correspondent

ONE of the most fascinating unsolved problems in palaeomagnetism is the source of the correlations between magnetic polarity and oxidation state found in rocks from certain sites. The construction of a polarity-time scale for the past 4.5 million years, the deduction from magnetic anomalies at sea that alternating periods of normal and reversed polarity extend backwards in time for many tens of millions of years, the evidence from baked contact rocks and the fact that about fifty per cent of the world's rocks are reversely magnetized, leave no doubt that almost all reversed rocks were produced during periods when the Earth's magnetic field was reversed. This being the case, there should be no correlation whatsoever between the magnetic polarity of rocks and their physical, chemical or mineralogical properties. Indeed, the existence of such correlations would be positive evidence for self-reversal, a phenomenon known to exist but support for which is overwhelmed by the evidence in favour of field reversal.

What, then, can be the explanation for the observed correlations? Reversed Quaternary and Tertiary lava flows from Iceland, reversed Tertiary flows from Japan

and reversed Carboniferous flows from Scotland all contain significantly more separate ilmenite than the normal flows from those sites; and statistically, the titanomagnetites in reversed Tertiary flows in Scotland, Iceland and the Columbia Plateau, Oregon, and in reversed dykes in Scotland are more highly oxidized than those in the corresponding normal rocks. The first question which needs to be asked is, of course, whether these correlations are fortuitous. After all, they represent a negligible proportion of the world's rocks, and many of these particular samples obey the classic tests for field reversal. The reason why so few correlations have been reported is simply that the work involved is long and tedious. Yet in spite of the small number, they share one property which argues against their arising by coincidence—they are all in the same sense. It is always the reversely magnetized rocks which are, on average, more highly oxidized, never the normal ones.

Even so, the significance of the oxidation-polarity correlations will ultimately be firmly established or rejected by statistics; and that is why a new report by Ade-Hall and Watkins (*Geophys. J.*, **19**, 351; 1970) is important. For these authors have carried out a petrographic and magnetic analysis of 168 Miocene to Pliocene basalt, ankaramite and phonolite lava flows from the Canary Islands, and find no correlation whatsoever between polarity and oxidation. There is, of course, always the possibility that the correlation really exists but is obscured in some way; but Ade-Hall and Watkins have carefully considered this problem and conclude that it does not arise here. It is possible, for example, that a collection which comprises three different rock types, each of which possesses a different but real polarity-oxidation relationship, might exhibit no overall correlation. A separate analysis for each rock type represented, however, revealed a correlation for none. Then again, it is possible that a correlation could be obscured by experimental limitations. It may, have been, for example, that the $\times 1200$ magnification used by Ade-Hall and Watkins in their petrographic analysis was insufficient to resolve fine exsolution of ilmenite in the titanomagnetite grains. This was also ruled out by low temperature Curie point measurements which failed to indicate the presence of any ilmenite at all.

So how does this new non-correlation affect the status of the oxidation-polarity problem in general? The answer is that by itself it makes little difference to the overall situation, for one brick is sufficient neither to build nor to demolish a structure. But it does have a two-fold importance. For one thing, it emphasizes, together with two other non-correlations, that oxidation-polarity relationships are not universal. This in turn serves to emphasize the statistical nature of the whole problem. And second, it stresses that, in this matter, negative results—the absence of correlation—are as significant as positive data. The long-term problem is, of course, that a vast amount of work will be necessary on other rock collections before it can be proved that the correlations observed hitherto are not trivial. But if the case is ultimately proved, it will be a major headache for Earth scientists. For, given the reality of field reversal, it is difficult at present to imagine what physical connexion there could be between the oxidation state of lavas which originate in the upper mantle and the magnetic field which is produced in the Earth's core.

COSMIC RAYS

Backing for Muon Theory

A NEW analysis of the spectrum of muons from cosmic rays at energies of more than 1,000 GeV has given added support to the notion that muons may be produced by way of a special "X process" involving a short lived intermediate particle. This idea was first put forward by H. E. Bergeson *et al.* (*Phys. Rev. Lett.*, **19**, 1487; 1967) to explain the unusual angular distribution of muons from cosmic rays detected in an experiment in Utah.

Bergeson *et al.* contended that the measured angular distribution was not consistent with the muons' being solely the byproduct of pions and kaons produced in the upper atmosphere. Some other process had to be invoked, and they suggested that the solution lay in what they called an X process, for which the variation with energy of muon production was flatter than for production from pions and kaons. One interesting possibility was that the X was in fact the intermediate boson, which is held to mediate the weak interaction but has so far eluded detection. Another view was that an integral charge SU3 triplet was responsible for the X process.

Bergeson *et al.* pointed out that the spectrum derived from a combination of muons from pions and kaons with those from the X process give—with one exception—a convincing fit to other cosmic ray data between 10^{11} and 10^{14} eV, and could also account for the existence of mu-less air showers at 10^{15} eV. There has, however, been some opposition to this scheme, given fuel by the need to assume that the photonuclear cross-section increases at energies of more than 1,000 GeV to five times the value that it has at normal accelerator energies, about 20 GeV.

P. Kiraly and A. W. Wolfendale (*Phys. Lett.*, **32**, 510; 1970) have shown that the presence of an X process need not depend on a large rise in cross-section. The weak link in the reasoning, they suggest, lies in the fact that the Osborne-Wolfendale-Palmer spectrum, which was the previously accepted muon scheme, was not measured directly by Bergeson *et al.* in this energy range but rested on the correlation of vertical cosmic ray intensity with depth underground and an assumed rate of energy loss. Kiraly and Wolfendale claim that if a higher rate of energy loss is taken the need for such a large cross-section is removed.

In the original analysis the X particles were assumed to have the same form of production spectrum as the pions and the vertical muon spectrum was derived from the angular distribution of the data. Kiraly and Wolfendale have followed recent practice by taking a larger constant in the energy loss formula. They also used the evidence from gamma ray experiments of a lower limit to the number of muons at sea level produced from pions. By then making the reasonable assumption that the number of muons produced by the X process is about 1.5 per cent of that from pions they show that the number of muons from pions at sea level can be made consistent with the evidence from gamma rays. This means that a big increase in photonuclear cross-section need not be a precondition of the existence of the X process. They also point out that the assumption of Bergeson *et al.* that the pion spectrum has the same slope as the primary spectrum is not necessarily true.

MATERIALS

Special Ceramics

from a Correspondent

RAPID advances in modern technology, for example in the nuclear power and gas turbine industries, are creating increasing demands for special materials with exceptional properties. Ceramists are turning to silicon nitride, silicon carbide and alumina, in that order, according to Dr N. F. Astbury, director of the British Ceramic Research Association, who gave the opening address at the Fifth International Symposium on Special Ceramics held in Stoke-on-Trent from July 14 to 16. Other papers at the conference dealt with pyrolytic materials, the fabrication of ceramic bodies and the determination of the physical and chemical properties of a wide range of materials.

E. Voice (Atomic Energy Establishment, Winfrith) described the deposition of pyrolytic silicon carbide from methyltrichlorosilane-hydrogen mixtures in a fluidized bed of carbon-coated nuclear fuel particles. He showed that the temperature and gas composition are critical for the production of a fully dense impermeable layer. The morphological aspects of such layers were discussed by D. E. Y. Walker (UK Atomic Energy Authority, Springfield Works), and J. Ashford and J. C. Hodgson (Central Electricity Generating Board, Berkeley) described a technique for determining the mechanical behaviour of the layers under static and cyclic stress.

Because of the difference in thermal expansion it has been impossible to obtain strong vacuum tight metal-silica seals without using "graded silica-glass" components. L. Verheyden, K. Klein and H. Kind (Euratom, Italy) showed that silica can now be joined directly to 'Kovar' (54 per cent Fe: 28 per cent Ni: 18 per cent Co) by using a composite wire with a core of titanium surrounded by a 72 per cent Ag: 28 per cent Cu alloy.

The fourth and final session of the symposium was devoted solely to silicon nitride ceramics. P. Grieveson with K. H. Jack and S. Wild (University of Newcastle upon Tyne) described techniques whereby, at a given temperature, the nitrogen and oxygen partial pressure required to form silicon nitrides and oxynitrides is accurately determined, showing that α and β are not low- and high-temperature forms but are "high oxygen potential" and "low oxygen potential" modifications. D. J. Godfrey working with M. W. Lindley (Admiralty Materials Laboratory, Poole) showed that reinforcement with carbon fibres or tungsten wire improves the toughness of silicon nitride tubes and increases the fracture stress. A novel technique for producing cellular silicon nitride was described by T. W. Lindop (Doulton Industrial Products). This low density material has many potential applications in the nuclear reactor and refractory industries. The results of an investigation by S. Wild, P. Grieveson and K. H. Jack (University of Newcastle upon Tyne) and N. J. Latimer (The Plessey Company) on the effect of magnesia additions on the hot-pressing behaviour of silicon nitride account for a number of previously unexplained features. At high temperatures, a liquid of composition near to that of enstatite (MgSiO_3) is formed and this acts during pressing as a flux and plasticizing agent to allow complete densification of the compact.

British Association—Durham, 1970

What is it all for?

WITH the cricket season drawing towards its close and with migratory birds about to make preparations for moving south, it is only natural that the British Association should once more be assembled, this time at Durham. There is no reason why the meeting should not be a modest success—the programme has been still further honed down, the sections seem to have been even more selective than in the past few years, while the North of England is known to be a generous supporter of all kinds of improving causes, the British Association among them. Unhappily, however, the association as a whole seems still to be divided within itself about its function in the modern world. Is it a scientific society or is it a public debating society?

The days are long since gone when a general interest in science could sustain and spur on the development of the several disciplines to which the British Association still devotes a section of its activity, yet there is evidently a less original but nevertheless important role to perform in carrying not merely news of new developments but a sense of their importance to the growing community of people with a professional interest in science, not necessarily in research. So much is beyond dispute, although the association still has some way to go before it can be thought to perform that task as expertly as circumstances require. So should the association set up also as a debating society? For one thing, there is no necessary inconsistency between such a function and its more traditional role as a purveyor of enlightenment. Indeed, there are many points at which the two interests should properly work together. Is there not, for example, a case for thinking that problems such as the proper siting of power stations or the uses to be made of supersonic air transports would be more easily resolved if there were a forum in which the facts and people's expectations of them could more directly be brought into confrontation with each other. In short there is room for a responsible debating society, and of course there is no reason why such a forum should become the kind of proceeding that turned the meeting of the American Association for the Advancement of Science, at Boston last Christmas, into what seems to have been a mixture of pantomime and student demonstration.

Not the least of the issues of public policy that needs to be taken up is the condition of scientific research itself. The pages which follow are designed so as to draw attention to some of the fields in which important and exciting developments have taken place in the past year. The number of topics could have been multiplied by two or three—there is nothing, for example, in what follows about the exciting developments which have kept astronomers on their toes for the best part of a decade. In the same way, the most recent and most fashionable of all the developments in molecular biology in the past few years—the demonstration of how the nucleic acid in RNA viruses can be used as a template for the manufacture of characteristic DNA—has been omitted from this survey, if only because the pages of *Nature* have been full of it for

weeks. And then the survey also neglects the important developments in those branches of physical science that are continually making a more intimate connexion between solid state physics and electronics, laser technology for example, the solid but important work on the borders of genetics and descriptive zoology that promises to throw an important new light on the dynamics of populations and indeed the whole concept of the balance of nature and the ways in which the craft of science is at last making its mark on the somewhat intangible problems that preoccupy the social scientists. The pages which follow describe, in short, the tip of an iceberg. Moreover, they show that the condition of science is—for the time being at least—as good as anybody could hope. This is why it is important to ask urgent questions about the steps that must be taken to ensure that scientific research remains in good health. The British Association should not shrink from playing its part in that important task. Not the least of the contributions it could make would be to demonstrate the importance of the role that scientific research continues to play in the modern world.

The most obvious threat to the condition of science is the prospect that funds for scientific research will not grow as quickly in the years ahead as the numbers of people leaving postgraduate courses at the universities and anxious to stay on in research. This is where most anguish has been caused in the past few months, in the United States especially. It is therefore important to recognize that the link between the scale of support and the pace of discovery is not nearly as simple as it sometimes seems. Doubling the amount of money for research on tumour viruses now that it seems as if there may be a few tangible points at which careful investigation may provide a route to the better understanding of some kinds of cancer will not, by itself, accelerate the pace of discovery by a factor of two or anything like it. On the other hand, there is a point at which the lack of money or other forms of support may seriously hamper the efforts of individual researchers, if only by distracting them from serious work. But the more important criterion for deciding the scale on which financial support for research is needed is bound up with poorly understood matters concerning the proper balance of the scientific community as a whole.

Thus there is a case for thinking that experienced investigators are more buoyed up by their work if they are

associated with younger people with whom they can share ideas and aspirations. Young people themselves seem to enjoy the competitiveness of research. And most people at all levels appear to be immensely stimulated by the connexion between research and education. It follows that a good many of the arguments about the exact amounts of money spent on scientific research at universities and elsewhere, which are the best approximations so far to what might be called a public discussion of science policy, are often well beside the point. Professor John Ziman (see p. 996) has done a great public service by drawing attention to some of the subtleties of the way in which the scientific community is organized. The first conclusion to be drawn from all this is that the capacity of the scientific community to sustain the momentum of its research is probably a good deal better than a mere counting of pennies would suggest. On the other hand, there are many ways in which a thoughtless handling of problems which seem peripheral to research as such may seriously damage the pace and the character of the original work being carried out. This is why discussions of the condition of science are inseparable from a consideration of the condition of the universities. It goes without saying that one of the most disturbing tendencies in the past few years has been that in which a good many universities in the west, and especially in the United States, seem in danger of losing the serenity from which, it seems, original work must spring.

But why should people worry if, by mishandling or misjudgement, the conditions in which original research is carried out should continue to deteriorate? This is the somewhat philistine question all too often asked by those on whom has fallen the responsibility for deciding whether to spend public funds on scientific research or some other public activity. In some sense, this is an issue that each person must settle for himself, and it is quite proper to ask whether the modern world would be substantially worse off without, for example, the understanding of sea-floor spreading about which Professor Vine writes on page 1013. And on the face of things, of course, it is a matter of largely academic interest that the continents

appear to drift about on the surface of the Earth—grist for the week-end magazines but hardly anything more than that. Only a little reflexion will show, however, what a shallow view that it.

The development of geophysics in a mere ten years is now well on the way to turning the whole of geology on its head. For one thing, it is now for the first time possible to understand the origins of the forces responsible for the great episodes of mountain building. The Himalayas, for example, are a measure of the northward movement of India in the past 100 million years. The African Rift Valley is now intelligible, and although dispute remains about the exact meaning to be given to the geological features of the Middle East, there is no doubt that its outstanding characteristics have been shaped by the pushing and pulling of the great tectonic plates. In exactly the same way, the seismic zones running the length of South America have been made intelligible. It can only be a matter of time before the consequences of the new tectonics for the more practical interests of the geologists are plain for all to see. But there is more than mere profit to be won from the new development. It is already clear that the new understanding of the way in which the surface of the Earth is being continually transformed has provided a new perspective for helping to make the real world rational and understandable. Like the great achievements in the past, it will help to drive away the cobwebs.

One of the most insidious dangers in the recent past has been the way in which the test of quality in science has been confused with the test of relevance. It would be a valuable exercise for those who raise the cry that scientific research should be directed towards practical ends to ask whether their present tests would have permitted the expenditure of public funds on the work which has now led to the new tectonics. The same embarrassment would be occasioned by the question whether the rest of the work described in this symposium would have qualified. Yet there can be no doubt that all of it will contribute in important ways to the more successful adaptation of people to the natural world. If the British Association needs an issue for which to fight, this would be a place to start.

Dunelm House, University of Durham, location of the General Symposia at the British Association meeting. The building was designed by Architects Co-Partnership and received the 1967 RIBA Architecture Award for Northern England (Region I). (Photo: John Donat.)

Investigations ranging from tissue culture to animal communication are rapidly providing deeper insights into the mechanisms of brain and behaviour.

DURING the past few years neuroscience, comprising the sciences of brain and behaviour, has been differentiating, integrating, regrouping, absorbing enthusiastic recruits from other sciences and sprouting many new conceptual growing points at all levels—molecular, cellular, neural, and behavioural.

There are indications of rapid expansion in the recent appearance of several journals and series of books with the words "brain" and "neuroscience" in their titles, and the formation of new multidisciplinary societies concerned with neuroscience. These include the Brain Research Association of the United Kingdom, the Society for Neuroscience of the United States, the European Brain and Behaviour Organization, and new speciality groups such as the International Neurochemical Society and the American Society for Neurochemistry.

I have chosen the topics for this brief review from recent work sessions, conferences and intensive study programmes—at each of the four levels mentioned—sponsored by the Neurosciences Research Program of the Massachusetts Institute of Technology, an international interuniversity organization for the stimulation of advance in neuroscience (details in ref. 1).¹

Properties of Membranes

The molecular biology of axonal and synaptic membranes is a crucial part of neurobiology². Sensitive and fast physical methods, such as polarization optics, light scattering and fluorescent probes are being applied in an effort to characterize the configurational changes of membrane molecules during excitation. Electron spin labels indicate the relative liquidity of membrane lipids, particularly those that are unsaturated, while proteins and carbohydrates confer solidity, according to McConnell³. The study of model systems of lipid bimolecular layers containing specific ion carriers has suggested a solution to a problem that has long eluded physiologists—how does the cell distinguish ions which are as similar physically and chemically as Na⁺ and K⁺ (refs. 4 and 5)? The ion carrier is pictured as an ion-specific peptide cage molecule that engulfs the cation, desolvating it as it enters, and closes by fast conformational change; then, facilitated by outwardly directed lipophilic side chains, the ion-bearing cage peptide traverses the membrane under the potential gradient and discharges the resolved ion on the cytoplasmic side of the membrane⁴. Isolation and characterization of the actual membrane carriers are difficult because of their low concentration in the neuronal membrane.

Histochemical and electron microscopic evidence has revealed glycoproteins attached to the membrane matrix. These have carbohydrate chains, which contain highly acidic sialic acid residues and extend into the intercellular space. Such glycoprotein cell coats at neuronal synaptic junctions may provide the specificity and molecular recognition by which the ontogenetically correct

neurones are synaptically linked; some investigators speculate that enzymatic changes of terminal glycosyl or fucosyl groups provide the plasticity for the consolidation of experiential information as learning^{7,8}.

Neuroplasmic Dynamics and Synapses

It is generally believed that neuroplasm is constantly synthesized in the cell body and moves as a gel down the axon (and probably also along the dendrites) at a rate of about 1 mm per day. Particular substances, for example neurosecretions—enzymes which synthesize transmitter—and vesicles are translocated differentially and much more quickly (100–2,000 mm per day)⁹. Translocation has been pictured¹⁰ as a saltatory interaction between enzyme-containing vesicles and fibrous proteins, chiefly microtubules—although neurofilaments may also be involved—with protein subunits which have been isolated and characterized chemically. The transport mechanism, probably universal in cells, is primitive and conservative evolutionarily. Chemomechanical coupling of energy may underlie this mechanism as it does contractility in muscle, cilia, flagella, and perhaps also the injection of nucleic acid into microorganisms by viruses.

Electron microscopy^{11,12} has revealed the detailed structure of synaptic junctions, which seem to be composed of a single type of material, presumably a protein still poorly characterized, which includes presynaptic dense projections (that enlarge with maturity and patency of the synapse), cleft-contained material, and a subsynaptic web. Vesicles slotted between dense projections are thought to release transmitter quantally by exocytosis through the membrane into the cleft.

Although only six substances qualify as transmitters, a dozen more may be discovered. Kandel *et al.*¹³, working with the synapses of the sea slug *Aplysia*, have shown that a given transmitter can excite some postsynaptic neurones and inhibit others, while a particular postsynaptic cell can respond to more than one transmitter. If generalization is justified, these features suggest that synaptic processing is more complex than has been supposed.

Drugs such as tranquillizers, antidepressants and psychotomimetics interact at particular synaptic sites; new compounds with highly selective actions are being synthesized for research into the mechanism of synaptic action. New drugs that have proved important clinically or pharmacologically are: 6-hydroxydopamine which selectively destroys adrenergic endings¹⁴; bicuculline¹⁵ which antagonizes the inhibitory transmitter GABA (gamma-amino butyric acid); and L-dopa (dihydroxy-phenylalanine), effective in the treatment of Parkinson's disease, which is converted into transmitter necessary for normal functioning, but is either missing or in low concentrations in Parkinson's disease.

The possibility that transmitter action is modulated or

controlled by macromolecules bound to presynaptic and postsynaptic membranes or released with transmitters into the synaptic cleft has been discussed recently¹⁶. There is particular interest in a protein called chromogranin A, which is present in the vesicles of the chromaffin cells of the adrenal medulla, and is valuable as a model for the study of transmitter metabolism, storage and release. Chromogranin—present also in the vesicles of adrenergic neurones, together with catecholamine, ATP and enzymes necessary for synthesis of noradrenaline—is thought to be extruded from varicosities and endings of sympathetic neurones. The elucidation of the function of the chromogranin protein may illuminate synaptic function further.

The nucleotide, adenosine 3',5'-phosphate (cyclic AMP), plays an important and newly discovered role as a "second messenger" in synaptic function¹⁷. The concentration of cyclic AMP in the brain can be increased forty-fold by electrical or neurohumoral stimulation¹⁸. When the receptor in the postsynaptic membrane combines with the neurotransmitter, it probably undergoes a change of configuration which is coupled allosterically with the activation of a membrane-bound enzyme, adenylyl cyclase, which converts intraneuronal ATP to cyclic AMP, and triggers off a metabolic chain of events in the postsynaptic cell. There is evidence that synaptic transmission in the cerebellum activates adenylyl cyclase, which links transmitter action with the cyclic AMP system.

McIlwain¹⁹ has pointed out that neurones contain a multiplicity of enzymes that can be induced thus, which means that their synthesis can be turned on genetically, in appropriate conditions; this large repertoire of enzymes with specific, adaptive inducibility may be as significant for brain processes (such as ontogenetic specification, adaptation, and plasticity) as is the ability to form a multiplicity of synaptic interconnections. Axelrod *et al.*²⁰ have demonstrated that the excitation of neuronal input can induce a high rate of synthesis of enzymes producing the transmitter noradrenaline. Peterson and Kernell^{21,22} have shown that presynaptic stimulation, but not excitation by antidromic invasion, of the giant neurones of abdominal ganglia isolated from the *Aplysia*, increased the postsynaptic synthesis of RNA. If RNA synthesized in these conditions generates specific proteins, a "permanent" response might thus result from synaptic excitation. Clearly there is a need to investigate gene expression, particularly adaptive enzyme induction and its association with membrane processes in neurones.

Neurogenetics and Neurogenesis

The study of neuroscience requires a simple animal capable of some degree of learning which, if systematically studied structurally, physiologically, behaviourally and genetically, could clarify basic problems in the way that microorganisms and viruses have done for molecular genetics. Several groups of investigators, including those led by Benzer, Brenner, Levinthal and Nirenberg, are studying small organisms such as the fruit fly *Drosophila*, nematodes and rotifers, which have only several hundred neurones. Many mutants have already been found, and the investigations seem to have started well towards the long term goal of correlating genetic, anatomical and behavioural parameters.

Several dozen strains of mutant mice have been developed (and the search is on for more) which, as a

result of systematic behavioural, anatomical and biochemical study, have given important information about cerebellar function, myelination and the mechanism of specification of neuronal patterns in systems such as the cerebellum and the cerebral cortex^{23,24}. For example, the excellent work done by Sidman relates the motor disorder in mutant "reeler" mice to improper positioning of neurones in the cerebellum, associated with a single gene mutation.

A second type of experiment²⁵ epitomizes the important results that are emerging from the *in vitro* study of brain tissue. Bits of cerebellum, cerebral cortex and hippocampus are dissociated into suspensions of isolated cells by the action of trypsin. When swirled in flasks of culture medium, the separated, rounded cells collide and manifest specific adhesivity and develop a histotypic organization which resembles the normal tissue from which they came. If the normal pattern of cells is to be reconstituted in this way, the age of the embryo when the tissue is dissociated and placed in culture is critical to within a day or less. Clearly, individual cell types within a particular tissue, such as cerebellum, are differentiated with respect to specific cell-cell adhesivity at precise times, so that the appropriate complex net connectivity develops serially.

This sort of experiment can give information about biochemical, immunological, morphogenetic and other parameters. For example, embryonic tissue taken from the cerebellum of a mutant mouse reeler fails to reaggregate histotypically after tryptic dissociation; the defective type of network characteristic of the cerebellar cortex of reeler is formed instead.

Cloning of brain cells, that is *in vitro* culture from a single parent cell, is opening important avenues of research. Cloned cells maintain their specific characteristics through many transplantation generations. It has been possible, for example, to show that a particular and well characterized acidic protein called 'S-100', which is specific to brain in all forms studied, derives primarily from glia rather than neurones²⁶.

Nirenberg and his colleagues^{27,28} have found that cells cloned from mouse neuroblastoma have many of the properties of differentiated neurones: they produce bioelectrically active membranes capable of propagating action potentials; respond to acetylcholine; grow processes containing microtubules and neurofilaments, and are equipped with the enzymes necessary to synthesize transmitters. This experimental design obviates the uncertainties resulting from chemical analysis of bulk neural tissue and facilitates the much-needed study of gene expression in neurones and the development of a neurochemistry and neuro-immunology of homogeneous cell types.

Retinal Physiology

New techniques for the intracellular injection of dyes and the detection of histofluorescence, together with electron microscopic and neurophysiological investigations of many vertebrate species, have characterized the five major cell types in the retina according to structure and physiology. Progress has also been made in tracing the processing of information from the time when light quanta are absorbed until the production of action waves in the optic nerve. It has emerged that information is processed in the retina without the generation of action potentials (spikes), but rather with slow potentials²⁹. Because the retina is an externalized bit of central

nervous tissue, these experiments raise the possibility that the slow-wave type of information processing is more important in the central nervous system than is commonly supposed. One of the five types of retinal cells, the amacrine cells, which lack axons, apparently participates importantly in neurophysiological processing (as in the olfactory bulb) and does so without spike generation³⁰. Adey has produced other evidence for the importance of slow-wave processes in the brain³¹.

Can Apes use Language?

Man's belief in his unique possession of linguistic capacities is being challenged by experiments with chimpanzees. Work of the Gardners³² with the chimpanzee Washoe, aged 5, and Premack³³ with Sarah, aged 8, has confounded doubts that chimpanzees can use arbitrary signs to refer to elements of the environment. They can do this if the signing does not require vocalization, for which they are poorly equipped, but instead requires manipulation, which they do well. Each chimpanzee reliably uses more than 100 signs—Washoe used the scheme known as the American Sign Language, and Sarah used plastic tokens—and each uses strings of several signs. Washoe generates "Please gimme sweet", and Sarah comprehends "If Sarah give apple Jim, Mary give cherry Sarah". Generally, their performance resembles that of 2 year old children. Even so, these achievements go far beyond anything previously demonstrated. It seems unlikely that the trainers are unwittingly cuing the correct responses. The deeper doubt is that, while chimpanzees can learn a sub-set of linguistic essentials, the full range of human semantic and syntactic powers is beyond them³⁴. Still, the capacities of these primates suggest ideas about possible stages in the evolution of language. Future physiological studies may isolate brain mechanisms of communication.

Relevance to Social Needs

Psychopharmacological experiments are beginning to yield data relevant to urban crowding as a health hazard. Mice under intense psychosocial stress caused by severe crowding produce enlarged adrenal glands with increase of adrenaline and noradrenaline and the enzymes necessary to synthesize these catecholamines²⁰. Although data obtained with animals cannot be applied directly to the human situation, it is possible that similar processes play a role in producing urban ghetto disturbances and other contemporary acute reactions to psychosocial stress.

The extensive use of various psychotomimetic substances by adolescents and young adults and the widespread addiction in suburbia to "energizing" and tranquillizing drugs pose problems that are growing with alarming rapidity. Basic and clinical research in neuroscience is needed badly to help alleviate the drug menace to society.

Violent and aggressive behaviour is an all too prevalent manifestation of social imbalance in many parts of the world. Much ethological and behavioural study has been devoted to the biological aspects of this problem. Brain stimulation, through implanted electrodes, has been applied to primates in normal conditions in the colony³⁵ and also to man in experimental conditions. Stimulation of one amygdaloid region of the limbic system may aggravate violent symptoms, while stimulation of a nearby region may tend to have a calming effect³⁶. Within the framework of acceptable medical, ethical and legal codes, clinical research is being joined with therapeutic treatment in some medical centres to investigate in humans

(the only subjects able to report emotional and subjective feelings) the neural, hormonal, biochemical and genetic mechanisms of aggressive and other aberrant behaviour.

The nervous system of the infant is susceptible to permanent injury by malnutrition and hormonal, genetic, toxic and traumatic effects³⁷. Brain damage due to nutritional deficiencies is probably much more widespread than is supposed. Postnatal psychological deprivation can cause irreversible damage³⁸. Some kinds of injury can be reversed by early treatment, and, happily, some forms of biochemical impairment (phenylketonuria, homocystinuria) can be prevented by adherence to the appropriate diet.

Clearly, neuroscience can contribute importantly to pressing social and medical problems which result directly or indirectly from harmful environmental influences and from inborn biochemical, neurological and genetic aberrations. Perhaps still more important to man's progress is the possibility of a better understanding of basic mental processes which, in the end, is responsible for the advancement of science and society.

The Neurosciences Research Program is supported by the National Institute of General Medical Sciences, US National Institutes of Health, the National Aeronautics and Space Administration, the Office of Naval Research, the Rogosin Foundation and the Neurosciences Research Foundation. I thank my colleagues on the NRP staff for helpful discussions and suggestions.

Second Golden Age of Molecular Biology

by

BENJAMIN LEWIN

The highlights of a year when microorganisms have proved more productive than ever for studying the genetic apparatus of cells have been the isolation and synthesis of DNA genes and the sequencing of RNA phage genes. First steps have been taken towards characterizing the enzymes which synthesize DNA and degrade RNA in bacterial cells. Protein synthesis in mammals is initiated in a way similar to bacteria; this supports the idea that the mechanisms of heredity are universal even in their details. A breakthrough in understanding the action of RNA tumour viruses has been the finding that they reverse the central dogma of molecular biology by directing synthesis of DNA.

A YEAR or so ago it was fashionable to say that the golden age of molecular biology had come to an end¹ and that research should now concentrate in other areas, such as genetic differentiation or neurobiology. But the advances of the past year have shown only too clearly that "classical" molecular biology cannot be disposed of so readily. Certainly, it is true that much of its conceptual framework is now firmly established and is unlikely to be overturned²; but after passing through a comparative plateau of discovery, bacterial protein and nucleic acid synthesis is turning out to be rather more complex than it seemed; and extension to higher organisms, and to their viruses, of the approaches used with bacteria is at last beginning to pay dividends.

Although there is now a depressing proliferation of control systems—it seems that one has only to think of a control system to find that it is used somewhere—the idea that there is a basic similarity between all organisms in at least their mechanisms of protein and nucleic acid synthesis is taking an increasing hold on the direction of research. Armed with a detailed knowledge of how proteins are synthesized in *Escherichia coli*, many research teams are looking to see whether the same processes work in more complicated organisms.

The most striking similarities are those between the various protein factors required for protein synthesis; in addition to the protein components of the ribosome itself, at least eight factors associate with it at particular stages of protein synthesis. The three factors concerned with the elongation of the growing polypeptide chain have been known for some time to fulfil closely related functions in *E. coli*, yeast, reticulocytes and rat liver. Factors to assist the termination of protein synthesis have so far been found only in *E. coli*, but there is no reason to suppose that, when found, they will prove to be much different in other organisms.

Initiation of Protein Synthesis

Despair that protein synthesis may start in different ways in different systems arose from the suggestion that N-acetyl-valine can initiate haemoglobin synthesis *in vitro*³, and that histones may start with N-acetyl-serine⁴; for in *E. coli*, protein synthesis is initiated only by N-formylmethionine. An AUG codon at the beginning of a gene codes for formylmethionyl-tRNA_i; this is a methionyl-tRNA in which the free amino group of the

amino-acid has been blocked by addition of a formyl group. *E. coli* cells also possess another type of methionine accepting tRNA (tRNA^{Met}_m), which cannot be formylated and which is used to provide methionine residues within proteins. For *E. coli* proteins which commence with methionine, the formyl group is subsequently removed from the nascent protein by a specific enzyme; and for proteins which commence with other amino-acids, the terminal methionine is also removed to reveal the proper N-terminal amino-acid⁵.

Hopes that most proteins may after all start in the same way have been revived by the finding at the MRC laboratory in Cambridge that mouse ascites tumour and liver cells contain two methionine tRNAs, one of which can be formylated *in vitro* by the *E. coli* transformylase enzyme, and the other of which cannot⁶. The formylatable species places methionine at the N-terminal end of proteins, and the non-formylatable species provides methionine for internal sites⁶. But although the two mouse methionine tRNAs seem to play roles analogous to those of *E. coli*, neither is formylated *in vivo*. The ability of the initiator Met-tRNA to be formylated may therefore be an evolutionary hangover.

Haemoglobin also seems to be initiated in a manner similar to bacterial proteins. Both the α and β chains of rabbit globin are initiated with a methionine residue which is removed during the early stages of polypeptide chain growth to reveal the physiological N-terminal amino-acid, valine⁷. As a similar mechanism initiates the synthesis of protamines (basic proteins) in trout testis cells⁸, this form of initiation may be in general use.

One problem raised by the existence of two types of methionine tRNA, each of which responds to the same codon (AUG), is how only the initiator tRNA responds to those AUG codons at the beginning of genes, but the internal coding tRNA responds within the message. In *E. coli*, the elongation factors which transfer tRNA to the ribosome recognize all normal aminoacyl-tRNAs, but do not interact with the initiator formylmethionyl-tRNA_i. Conversely, the factors involved in initiation bind only the initiator tRNA and no other aminoacyl-tRNA. Reticulocytes probably have a similar mechanism, for their initiation factors preferentially bind initiator Met-tRNA and their elongation factors discriminate against this tRNA⁹.

Ribosomes also must be able to distinguish AUG initiator codons from AUG triplets within messengers,

perhaps by recognizing some nucleotide sequence somewhat longer than the AUG codon itself. The most promising approach to resolving the dilemma of the ribosome in deciding the meaning of AUG codons has come from the sequencing of RNA phages. The f2 phages have as their genetic material a molecule of RNA some 3,500 nucleotides long which comprises three genes; these code for maturation protein, coat protein and an RNA replicase which reproduces the phage. More than 500 residues have been sequenced during the past year, including the regions at each end of the RNA molecule, the initiation regions at the beginning of each of the three genes, the termination region of the coat protein gene, and also a considerable proportion of the internal region of this gene.

The initiation regions of the three genes have been characterized by allowing ribosomes to bind to the RNA phage to form an initiation complex. Treatment with nuclease then destroys the RNA molecule, except for the initiation sequences, which are protected by the ribosome binding¹⁰. All the initiation sequences have an AUG codon, and curiously, all also have a UGA termination codon in phase a few triplets before the initiator codon. But there seems to be no extensive similarity in the sequences bound to the ribosome. This means that there may be more than one type of ribosome recognition sequence on a messenger, and this could act as a control over its translation.

The chain termination sequence of the coat protein gene contains two different terminator codons in immediate succession, UAA UAG¹¹. The general significance of this redundancy is not clear, but the proper termination of proteins may be so important that this is a precaution against the suppression of termination that takes place when certain tRNAs are mutated so as to recognize nonsense codons instead of their proper codons.

An intriguing result of the sequencing is that there seem to be large stretches of the phage that are not translated into protein. As well as regions at each end of the phage (at least the first 100 nucleotides at the 5' end, and at least the last 50 at the 3' end) which do not code for protein, there are untranslated sequences separating the genes. Phage Q β , an RNA phage unrelated to the f2 group, also has a long (175 nucleotides) untranslated 5' terminal region¹². So far as can be judged from the sequences now known, the f2 phages have an extensively ordered secondary structure with many hairpin loops. Although it may be somewhat easier to discover their functions when the complete phage sequence is known, one possible role for the untranslated regions and secondary loops may be to control the translation of the phage RNA into protein (see *Nature*, **226**, 1093; 1970). In spite of some speculation, however, there is no reason to suppose that this sort of control mechanism also applies to bacterial messengers.

Control of RNA Synthesis

Protein factors are making their presence felt in virtually every area of molecular biology. Until very recently, almost all that could be said about the mechanism of RNA transcription was that it is catalysed by the enzyme RNA polymerase. But it is now clear that although the basic enzyme possesses the catalytic activity which synthesizes phosphodiester bonds, the initiation and termination of transcription are assisted by protein factors. The precise role which the termination factor, rho¹³, plays *in vivo* is muddled at present, for *in vitro*,

at any rate, there is more than one way in which RNA synthesis can be terminated (see *Nature*, **226**, 1093; 1970).

The RNA polymerase of *E. coli* is a multimeric protein, one subunit of which, the sigma factor, is concerned with the initiation of RNA synthesis. The sigma factor is released from the RNA polymerase-DNA complex as soon as synthesis of the RNA chain has begun, leaving the task of transcribing DNA into RNA to the remaining subunit complex, the core enzyme². It is the sigma factor which determines the specificity of transcription; the core enzyme by itself can use DNA as template for the transcription of RNA, but does so by transcribing only random segments of the genome. When the sigma factor is present, by contrast, transcription takes place only from certain starting points (promoters)¹⁴.

But the role of sigma extends beyond merely restricting the core enzyme to transcribing certain bacterial genes, for more than one such factor has been identified. It is true that there is only one sigma factor in bacteria, but the production of further such factors plays an important role in bacteriophage infection. When a T4 bacteriophage infects an *E. coli* cell, only certain parts of its genome (the immediate early genes) are transcribed. This is because the *E. coli* sigma factor recognizes only their promoters¹⁵.

One of the first proteins synthesized after phage infection is another sigma-like factor, which displaces the bacterial factor and directs the core enzyme of the host cell to synthesize RNA from a different set of bacteriophage genes (the delayed early genes)¹⁶. During infection, some of the subunits of the host enzyme are modified; although this does not affect which early genes are transcribed, one function of this modification may be to change the affinity of the core enzyme for sigma-like factors, so that later in infection it associates with a second phage-coded sigma-like factor; the production of this sigma factor results in transcription of another set of bacteriophage genes (the late genes) (see *Nature*, **226**, 1093; 1970).

Killer Ribosomes

Bacterial messenger RNAs are notoriously unstable, with half lives of a few minutes only. But although a good deal is known about the synthesis and translation of mRNA, it has proved more difficult to characterize the enzyme(s) which must be responsible for its degradation. Almost all that is known for sure about messenger breakdown is that the degradation of a messenger seems to follow, as it were, the tightly packed cluster of ribosomes which translates the message. As the ribosomes themselves follow closely after the RNA polymerase which is synthesizing the messenger, this means that degradation at one end begins even before the far end has been synthesized².

Many ribonucleases have been found in *E. coli*, but that responsible for degrading messengers has remained remarkably elusive. The fifth ribonuclease to be found (ribonuclease V), however, has at least some of the required properties¹⁷. This enzyme seems to be part of the ribosome and degrades mRNA from 5' to 3' in a sequential manner; it is specific for mRNA and does not attack rRNA. The enzyme activity requires all the components necessary for the movement of ribosomes along messengers and is inhibited by inhibitors of protein synthesis. This may mean that some fixed proportion of ribosomes contains this enzyme, and when one of these "killer" ribosomes attaches to the message, it degrades

the mRNA as it moves along at the end of the cluster of ribosomes.

But the isolation of what may be a mutant in a messenger-endonuclease lends credence to the idea that the degradation of mRNA may not always be as simple a process as the molecular biologist would hope. The existence of this enzyme has been inferred from the finding of a mutant which relieves polarity in *E. coli*. Polarity is the term coined to describe the observation that a nonsense mutant in one gene of a bacterial operon may have two effects; as well as inactivating the protein coded by the gene in which it occurs, it may also cause a reduction in the amount of (normal) protein(s) synthesized by genes subsequent to that mutated². Although polarity is at least partly caused by the reduced translation of the portions of the polycistronic messenger beyond the nonsense codon (presumably because the ribosome dissociates from the message at the nonsense site), transcription may also be affected. The messenger representing the operon in such cases is smaller than usual because it lacks the segment corresponding to the part of the operon beyond the mutant site. Two explanations have been proposed to account for this; transcription as well as translation may for some reason come to an untimely end at the nonsense codon so that the distant part of the messenger is never synthesized; or this part of the messenger may be synthesized, but is broken down so fast by nuclease action that it is not available for translation.

The distant part of the messenger might be defenceless before the onslaught of the nucleases because the ribosomes which would protect it from such an attack have dissociated from it at the nonsense mutant site. This theory would require an endonuclease to be involved in messenger degradation, because the first section of the mRNA would be protected by the ribosomes translating it. Support for this idea comes from the finding of a mutant of *E. coli* in which polarity is generally relieved; in the tryptophan operon, at least, this relief is associated with the reappearance of the messenger corresponding to the distant parts of the message¹⁸. This could be explained if the mutant had an inactive messenger-endonuclease. After the message had been cleaved internally by the endonuclease, a second enzyme could degrade the fragments released; this enzyme would not need to work in the 5' to 3' direction, but could perhaps work backwards from the site of cleavage in a 3' to 5' direction.

Elusive Replicating Enzymes

The most central issue of molecular biology is perhaps that of how the genetic material is replicated. A good deal is known about the mode of DNA replication²; it is semi-conservative (probably taking place by unwinding of the two parental strands, each of which then synthesizes a complementary strand by base pairing); the accuracy of the process does not depend entirely on the specificity of hydrogen bonding between base pairs but is to some extent influenced by the replicating enzyme(s); it is discontinuous, each of the new DNA strands being made in short fragments which are only subsequently covalently linked together.

But although some of the ancillary enzymes and genes involved in replication have been identified (such as the polynucleotide ligase which joins together the discontinuous segments), the enzyme(s) which actually replicate the DNA remain elusive. The Kornberg DNA polymerase, long hailed as the replicating enzyme, will, it is

true, replicate DNA *in vitro*, but the manner in which it does so does not support the idea that it replicates DNA *in vivo*. This enzyme prefers single stranded DNA as template, and does not work well when duplex DNA is its substrate.

Suspensions that the Kornberg enzyme may be concerned with the repair of damaged DNA in the cell and not with replication have hardened with the characterization of the many catalytic activities which it can undertake *in vitro*¹⁹, and with the isolation of a mutant of *E. coli* which lacks the enzyme activity when assayed *in vitro*. DNA polymerase can not only synthesize DNA *in vitro*, but can also hydrolyse the strands of a DNA duplex in either direction, or can instead use pyrophosphate ions to achieve pyrophosphorolysis in a 5' to 3' direction. Even more significant, DNA polymerase can excise thymine dimers from DNA *in vitro* (the covalent linking of adjacent thymines into a dimer is the major result of ultraviolet irradiation of cells) by releasing them into the cell supernatant in oligonucleotide fragments²⁰. Clearly, these activities would be useful for an enzyme with the cellular function of removing and replacing damaged parts of DNA, but seem less necessary for one concerned only with the replication of DNA.

But the demonstration that DNA polymerase has some function *in vitro* is no longer convincing as evidence that it does so *in vivo*. A surer guide would be to see what cellular properties are impaired by a mutation in the gene for DNA polymerase. Such a mutant was isolated by assaying many mutagenized clones of *E. coli* for DNA polymerase activity *in vitro* until one proved defective²¹; in spite of its defect, the Cairns mutant can grow normally and replicate its DNA. But it is five times more sensitive to ultraviolet light than is its parent strain, supporting the idea that *in vivo* DNA polymerase is concerned with the repair of damaged DNA²². It is not yet clear just which enzyme functions are impaired in the mutant, for it retains a normal ability to excise thymine dimers from its DNA²³. After ultraviolet irradiation, however, the mutant degrades its DNA to a greater extent than does the wild type, in a way which suggests that this degradation is due to an exonuclease. The mutant may have a DNA polymerase, therefore, which although unable to synthesize DNA can still degrade it, but in which this latter activity has somehow been altered.

If DNA polymerase does not replicate DNA, what does? The identification of other enzyme systems *in vitro* has proved difficult because the activity of DNA polymerase obscures any other DNA synthesizing activities. But two systems which lack DNA polymerase activity and can nevertheless replicate DNA have now been developed at the Max Planck Institute in Tübingen. One preparation uses a procedure in which DNA polymerase can be washed out of the preparation²⁴, and the other has made use of the Cairns mutant defective in the enzyme²⁵. Both comprise membrane-protein fractions of *E. coli* which can replicate DNA semi-conservatively at a rate comparable to that prevailing *in vivo* (DNA polymerase works only much more slowly).

The idea that DNA replication may take place at a complex associated with the membrane of the cell first arose from evidence that the origin (where replication starts) and the growing point (the present location of the replicating enzyme(s)) of bacterial chromosomes seem to be associated with the cell membrane². One possibility is that replication may not be catalysed by a single enzyme, such as DNA polymerase, but may instead

take place at a replicating complex consisting of many enzymes and associated with the cell wall (much as protein synthesis is accomplished by the enzyme complex comprising the ribosome). The task of identifying individual replicating enzyme activities may prove to be very difficult if it turns out that the complex (if it exists) can function only as a whole, and cannot be analysed enzyme by enzyme.

Isolation and Synthesis of Genes

Although the spectre of genetic engineering was raised by the isolation and synthesis of specific genes, neither of these events really marked much advance towards the prospect of new genes for old humans. The isolation by Beckwith's group at Harvard of the pure DNA carrying the genes for much of the lactose operon of *E. coli* is notable for the elegance of the experimental technique²⁶. Essentially, this involved adding the bacterial genes to the DNA of two bacteriophages in such a way that when the corresponding single strands of the duplex DNA of the two phages were prepared, each strand carried one of the two strands of the DNA of the lactose operon. The bacteriophage strands were therefore complementary in the sequence for the lactose genes only, so that hybridization of the two sets of strands gave duplex DNA corresponding only to the bacterial operon.

The isolation of much of the lactose operon in pure form, including two of its control elements, the operator and the promoter, will be invaluable in studying the nature of the interaction between proteins (such as repressors or RNA polymerase) and DNA. How a protein can recognize a sequence of base pairs in DNA remains one of the main unsolved puzzles of molecular biology. How the activity of the lactose operon is controlled is also turning out to be rather more complicated than anyone had suspected until very recently (see *Nature*, **226**, 1093; 1970), and a defined system to work with cannot be but useful.

But this type of approach is limited by its very nature to bacterial systems, where a bacteriophage may pick up a small and specified segment of the genetic material of its bacterial host. In lieu of any comparable system in the cells of higher organisms, there would seem to be no prospect whatsoever of extending a similar approach to them.

Khorana's synthesis at Wisconsin of the gene which codes for yeast alanine tRNA²⁷ is perhaps as much of symbolic as of immediate practical value. The properties of the product transcribed from this gene will certainly yield some interesting information about transfer RNA, but this is not the only way to study the synthesis of tRNA. Certainly, the synthesis of a DNA sequence corresponding to a tRNA is not in itself as important as will be the future extension of the techniques which Khorana has pioneered to the synthesis of other genes, and perhaps to their linking together into polygenic pieces of DNA.

Making a gene which codes for a protein may prove to be more difficult; even the smaller proteins would demand rather larger genes—insulin, for example, would have to be coded by a gene some twice the size of that for alanine tRNA. And the ready transcription and translation of such genes is by no means assured until the nucleotide sequences of the signals for starting and stopping transcription and translation are known. The idea that the day will soon come when extra pieces of DNA can be synthesized and added at will to the genome

of higher organisms to repair their defects is not only naive but also wrong-headed.

Dogmas and Heresies

The reverence with which DNA is regarded as the repository of genetic information in the nucleus has come under some attack in recent months. First came the proposal that DNA is present in the cytoplasm of cells of higher organisms²⁸, where it might fulfil functions analogous to those of messenger RNA. But this "information"-DNA has now fallen by the wayside, for further experiments have shown its presence in cytoplasmic extracts to be an artefact of the preparative procedures used²⁹.

The abrogation to RNA of some of the properties previously reserved for DNA has, however, proved rather more successful. The fastest rolling bandwagon ever seen even in molecular biology must surely be exploitation of the discovery that RNA tumour viruses can act as templates for the synthesis of DNA^{30,31}. Perhaps the winner of this race—if there is to be a winner—will entertain us with a counterpart to Watson's exposé in *The Double Helix*.

The RNA-dependent DNA polymerase contained in the virion of RNA tumour viruses seems to catalyse the synthesis of an RNA-DNA hybrid, using the RNA genome of the virus as template for the synthesis of a complementary strand of DNA^{32,33}. So far, the extent of hybrid formation has been shown to correspond to only a small part of the viral genome, but even so, it seems probable that hybrid formation serves as a first step towards the synthesis of a duplex DNA, corresponding to at least some of the viral genes, which can be integrated into the genome of the host cell. Other enzymes would be needed to complete this process; the virion also contains a DNA polymerase which can replicate duplex DNA and may be one of them³⁴.

It is too early to say whether this mechanism has evolved especially to enable the genetic information coded by RNA tumour viruses to be integrated into the cell genome, or whether similar information retrieval systems exist in uninfected animal cells. If there is no counterpart in the host cell to these viral enzymes, it should prove possible to inhibit selectively the action of the virus without harming the host cell.

The ease with which this discovery has been fitted into the existing conceptual framework of molecular biology shows just how little it has really upset present ideas. There is, after all, a ready way for DNA sequences to be derived from RNA. The synthesis of DNA from RNA templates will doubtless prove to be more useful for study of the unusual enzyme systems which reverse the normal relationship between template and product in nucleic acid synthesis than it will for the demolition of the central dogma.

The central dogma, enunciated by Crick, the high priest of molecular biology, has long been taken to say that the flow of genetic information from DNA through RNA to protein is a one way process which cannot be reversed. Certainly, in formal terms this idea is no longer valid. But this is of little import in more practical terms. The ultimate heresy—which would require a drastic rethinking of the whole conceptual basis of molecular biology—would be the retrieval of genetic information from protein to nucleic acid³⁵. But of this there is no sign yet.

The Geophysical Year

by
F. J. VINE

School of Environmental Sciences,
University of East Anglia

During the past year the results of deep sea drilling and other geophysical investigations have continued to strengthen the concepts of sea floor spreading and plate tectonics. Samples of lunar rock, too, have focused attention again on the history of the Earth.

1969-70 has been yet another year of spectacular advance and rejuvenation within the Earth sciences, although with the advent of lunar exploration and its associated scientific programme the term Earth sciences is something of a misnomer. The profession is buoyed up not only by the return of rock samples from the Moon and the ability to carry out physical experiments and observations on the lunar surface, but also by a plethora of results from the successful deep sea drilling programme, and the insight being gained into all aspects of geology through the pursuit of the unified concepts of sea floor spreading, plate tectonics and continental drift.

The concept of sea floor spreading was essentially a phenomenon of the 1960s; formulated by the late H. H. Hess of Princeton in 1960 and finally confirmed beyond reasonable doubt by the results of the first phase of the JOIDES deep sea drilling project in 1969. This single, revolutionary and elegant hypothesis simultaneously revived the older, but largely rejected, concept of continental drift and paved the way for the more modern and even more potent concept of plate tectonics.

Briefly, Hess¹ postulated that, as a result of convection in the Earth's mantle, the deep ocean basins are young and ephemeral features of the Earth's surface, constantly being regenerated at mid-ocean ridge crests, which are situated over mantle upwellings, and destroyed beneath the marginal trenches and island arcs which are the "sinks" in the system (Fig. 1). If such an upwelling were initiated beneath a continental area, the continent would be rifted and "drifted" apart and an intervening ocean basin formed as a result of lateral and symmetrical accretion of new ocean floor to the rift flanks; the rift ultimately becoming a mid-ocean ridge crest. The Atlantic and Indian Oceans might have been formed in this way during the past 200 million years, resulting in the separation of the surrounding continents, and implying average rates of lateral accretion or "spreading" of the ocean floor of 1-2 cm/yr. The East Pacific Rise might also be a

spreading ridge but initiated within a former oceanic area and therefore not constrained to be in a median position within the Pacific Ocean basin.

Magnetic Anomalies give Time Scale

In 1963, Matthews and I suggested² that sea floor spreading might be recorded in terms of the disturbances or "anomalies" in the Earth's magnetic field recorded over the ocean basins. If the Earth's magnetic field has reversed its polarity in the past then such reversals, coupled with spreading, would produce "avenues" of normally and reversely magnetized crust parallel to and symmetrically disposed about the mid-ocean ridge crests. The magnetization contrasts between these avenues would be capable of producing appreciable disturbances in the magnetic field at or above sea-level as measured by a ship or aircraft. By 1966 a geomagnetic reversal time scale had been deduced empirically for the past 3.5 million years from detailed palaeomagnetic and dating studies of subaerial lava flows and deep sea sediment cores. With the definition of this reversal time scale it was possible to demonstrate that the magnetic anomalies associated with ridge crests can be explained in terms of symmetrical spreading at essentially constant rates during the past 3.5 million years³. The distance from the ridge axis at which particular reversals are recorded makes it possible to deduce rates of spreading for all ridge crests for which magnetic data are available. Rates deduced in this way are indicated in Fig. 2 by the separation of the pair of solid lines adjacent to the dotted lines at the ridge crest. Integrated along the whole length of the mid-ocean ridge system these rates imply the formation of new oceanic crust at a rate of $2.6 \pm 0.2 \text{ km}^2/\text{year}$ (ref. 4).

The technicalities of both lava flow and sediment methods for determining the age of geomagnetic reversals are such that neither can extend the time scale back beyond 3.5 million years very readily or precisely. But the same sequence of magnetic anomalies away from ridge

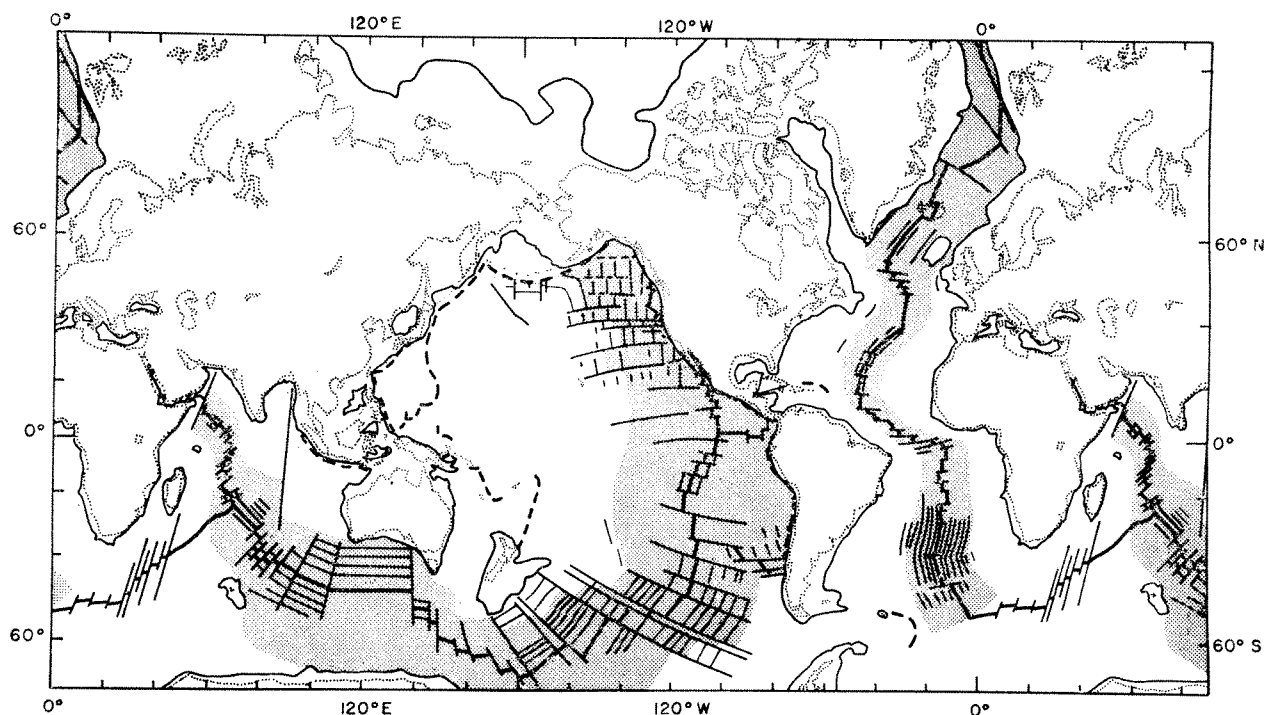

Fig. 1. Provisional attempt to delineate areas of continental and oceanic crust. Within the ocean basins, trenches are indicated by thick dashed lines, ridge crests by thick solid lines, and fractures (transverse to the ridge crests) and correlateable linear magnetic anomalies (parallel to the ridge crests) by thin solid lines⁵. Oceanic crust formed within Cainozoic time (that is the past 65 million years) is shaded.

crests is observed for thousands of kilometres across ridge flanks in all the major ocean basins implying that spreading and reversals of the Earth's magnetic field have occurred throughout an appreciable proportion of geological time. Areas in which this sequence of anomalies has been documented are summarized by families of parallel lines in Fig. 1 (ref. 5). To assign provisional ages to the older magnetic anomalies and thus to the underlying oceanic crust and to the implied reversals of the Earth's magnetic field, Heirtzler *et al.*⁶ assumed a constant rate of spreading of 2 cm/yr/ridge flank (that is, that deduced from the central anomalies) in the South Atlantic. In this way they were able to draw 10 million year "growth lines" for this and all other ridges across which the anomaly sequence has been recognized (Fig. 1).

Thus the confirmation of Hess's hypothesis in terms of the magnetic anomalies led to very specific predictions about the age and history of the ocean basins. With the advent of the US Deep-Sea Drilling Project two years ago it became possible to apply a very rigorous test of these speculations. In particular the primary objective of leg III of this so called JOIDES project was to test the spreading hypothesis and proposed geomagnetic reversal time scale. Eight sites were drilled across the Mid-Atlantic Ridge in the South Atlantic at approximately 30° S, and beneath the previously dated magnetic anomalies (Fig. 1). At all but one site the complete sedimentary column was penetrated and basalt "basement" recovered. Remarkably the palaeontological age of the oldest sediment recovered at each site, that is, immediately overlying or incorporated within the basalt, was found to be directly proportional to the distance of the site from the ridge axis⁷ (Fig. 3). Thus spreading about the South Atlantic ridge seems to have been continuous throughout the Cainozoic and at an essentially constant rate of 2 cm/yr/ridge flank, precisely the assumptions made by Heirtzler *et al.*⁶ in assigning ages to the magnetic anomalies.

This confirmation of the provisional ages assigned to the oceanic crust makes it possible to estimate the area of deep ocean floor formed by spreading during the Cainozoic, that is, the past 65 million years, as shown by the shaded area in Fig. 1. This necessitates considerable interpolation in the equatorial Pacific and Atlantic, where the magnetic anomalies are poorly developed because the Earth's magnetic field is essentially horizontal and parallels the trend of the ridge, but is probably quite an accurate estimate. It leads to the startling conclusion that perhaps 50 per cent of the present deep sea floor, that is, one-third of the surface area of the Earth, has been created during the most recent 1.5 per cent of geological time.

It seems extremely probable that all remaining oceanic areas are no greater than Mesozoic in age (that is, they were formed within the past 225 million years). The JOIDES drilling ship *Glomar Challenger* has occupied about 120 sites in the Atlantic and Pacific oceans and is currently in the Mediterranean; at no site so far has the age of the material recovered conflicted with the concept of sea floor spreading. In the western Pacific and western North Atlantic several sites were specifically chosen in the hope of sampling some of the oldest sediment in the ocean basins. The oldest sediment recovered, however, is middle Jurassic in age (that is, about 160 million years old). This was obtained recently in several holes just north of the Bahama Bank in the western North Atlantic⁸, and fits well with the previously suggested age of 180–190 million years for the initiation of drift between the east coast of the United States and north-west Africa^{9,10}.

It is now becoming apparent from palaeomagnetic studies on land that during the late Mesozoic or Cretaceous period (65 to 135 million years ago) there were very few reversals of the Earth's magnetic field¹¹. This is in great contrast to the Cainozoic, and would explain why areas of presumed Cretaceous ocean floor, for example, in the

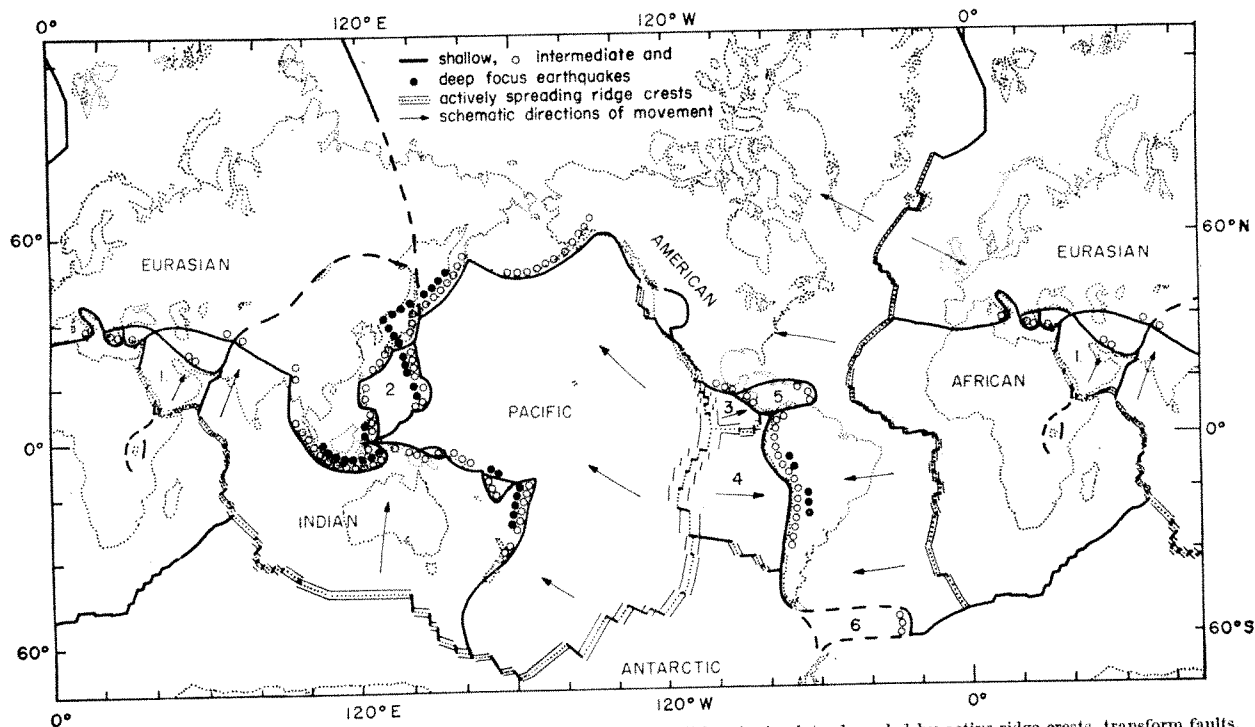

Fig. 2. Summary of the seismicity of the Earth²¹, and thus of the extent of lithospheric plates bounded by active ridge crests, transform faults, trench systems and zones of compression. The six major plates are named; the following minor ones are numbered: (1) Arabian; (2) Philippine; (3) Cocos; (4) Nazca; (5) Caribbean; (6) Scotia. Spreading rates at ridge crests are indicated schematically and vary from 1 cm/yr/ridge flank in the vicinity of Iceland to 9 cm/yr in the equatorial Pacific Ocean.

vicinity of Hawaii and along the margins of the South Atlantic, are "quiet" magnetically and devoid of correlatable linear anomalies. (The South Atlantic is thought to have opened up 110–120 million years ago^{9,10}.) To the southeast of Japan^{12,13} and in the North Atlantic, off the coast of the United States¹⁴ and northwest Africa¹⁵, linear magnetic anomalies have been mapped over even older ocean floor and are thought to reflect geomagnetic reversals during Jurassic, that is, mid-Mesozoic, time.

As I have already intimated, sea floor spreading has been superseded within the past few years by the even more potent and successful concept of plate tectonics. This has derived from a better understanding and more detailed consideration of the geometry of spreading and the seismicity of the Earth, the two phenomena being intimately related.

In 1965 J. Tuzo Wilson¹⁶ noted that within the framework of sea floor spreading a new class of faults or fractures in the Earth's crust is possible, their seismically active lengths terminating at ridge crests or trench systems (Fig. 2). This formulation of "transform faults" led to the realization by Morgan¹⁷, and McKenzie and Parker¹⁸ that the world-wide geometry of spreading and drift can be expressed, to a first approximation, in terms of relative movements between a limited number of rigid plates bounded by ridge crests, trench and mountain systems, and transform faults (Fig. 2). In a sense this is no different from the assumption made by Carey¹⁹ and Bullard *et al.*²⁰ in fitting together the Atlantic shelf edges of Africa and South America, but the plate tectonic hypothesis is more general. Thus the current seismicity of the Earth²¹ defines the current tectonic activity in the form of spreading and crustal tension at ridge crests, underthrusting and compression in the trench and mountain systems, and lateral translation without change in surface area along transform faults. Because the direction and rate of

spreading at ridge crests can be determined from the transform faults and magnetic anomalies respectively¹⁷, it is possible to make a global analysis of plate movements and predict the direction and rate of underthrusting in the trench and mountain systems²². Such directions are found to correlate well with the slip vectors deduced from focal mechanism solutions for some of the larger shallow earthquakes, and the rates with the maximum depths to which earthquakes occur beneath the trench systems²³. Presumably the latter reflect a thermal relaxation effect as

Fig. 3. The age of the oldest sediment recovered at each site plotted against the distance of the site from the ridge axis. With the exception of sites 17 and 18 all sites were drilled to the west of the ridge axis. The diamonds indicate the estimated error in the age and distance determinations. Basalt basement was not reached at site 21 (ref. 7).

cold oceanic crust and upper mantle is thrust down into hotter mantle and gradually assimilated.

It can now be seen that the earlier terms continental drift and sea floor spreading are inappropriate in that individual plates typically include both continental and oceanic crust, although a few are entirely oceanic (Fig. 2). Moreover, it has been realized that the Earth's outermost skin, or "lithosphere", which has appreciable strength and rigidity, extends well beneath both continental and oceanic crust to a depth of approximately 70 km²⁴. At ridge crests the lithospheric plates are thinned by the elevation of the geotherms as a result of mantle upwelling and emplacement; beneath the trench systems the oceanic plate plunges downward, typically at an angle of about 45° to the other plate, as indicated by the deep focus seismicity²⁵ (Fig. 2).

Plate Tectonics

The past year has seen important new developments and applications of the concept of plate tectonics. Its originators, McKenzie and Morgan, have collaborated²⁶ to formulate the geometry and evolution of triple junctions: points at which any combination of the three elements, ridge crests, transform faults or trenches come together. Of the various permutations perhaps the ridge-ridge-ridge type is the simplest. There is at least one example of such a triple junction within the present ocean basins, to the west of the Galapagos Islands (Fig. 2). Surprisingly, neither this nor other present day triple junctions had received much attention until recently. That to the west of the Galapagos Islands was investigated by scientists from Princeton University and the US Naval Oceanographic Office last May (reported in the *New York Times* on July 9, 1970) and seems to have a simple geometry, as predicted by plate tectonics, and a spectacular bathymetric expression. These findings lend added credence to the suggestion of Pitman and Hayes²⁷ and Hess and myself¹⁰ that the so called magnetic bight of the North Pacific, immediately south of the Aleutian Islands (Fig. 1), was formed at a triple-ridge junction approximately 65 million years ago.

Regional studies of seismicity, including focal mechanisms solutions, continue to verify the essentials of plate theory and to add details in complex areas. Recent areas studied include the East and West Indies^{28,29}, the Red Sea³⁰ and a particularly instructive analysis for the complex Mediterranean area by McKenzie³¹. The plate boundaries deduced by McKenzie for the eastern Mediterranean are incorporated in Fig. 2. With the definition of the geometry of transform faults and ridge crests along the Chile Rise^{32,33} only one major length of the mid-ocean ridge system remains inadequately defined. This is the south-west Indian Ocean ridge to the south-east of South Africa. Recently a South African expedition made a limited but detailed geophysical survey in the vicinity of Marion Island which may well provide this final piece of the jig-saw puzzle. Earlier data on the bathymetry, magnetism and sediment distribution across this ridge suggest that it is either dormant³, or was rejuvenated recently and is spreading very slowly. The latter is perhaps more probable, for the ridge crest is quite active seismically.

Island Arcs

An interesting and important new development within the context of sea floor spreading and plate tectonics is the suggestion that a process equivalent or analogous to

spreading at ridge crests may be occurring, probably on a more limited scale, behind island arcs. This concept has been documented in considerable detail for the Tonga-Kermadec arc by Karig³⁴ who suggested that it might also be applicable to the Marianas and other island arc systems with comparable morphologic provinces. Just more than a year ago, on JOIDES leg VI, two sites were drilled in the Philippine Sea on the inner arc behind, that is, west of the Marianas arc. These provided rapid confirmation of Karig's hypothesis in that they revealed a stratigraphy comparable with that beneath Guam on the arc proper, the intervening basin being flooded by a very thin veneer of sediments with presumably a very young volcanic basement beneath³⁵. It is not known whether such areas are characterized by linear magnetic anomalies, but it seems probable that the process of formation of this new oceanic crust is somewhat analogous to that occurring at ridge crests, although it may be taking place more slowly and over a broader and more diffuse zone.

In spite of the vast accumulation of near-surface evidence in favour of the hypotheses of sea floor spreading and plate tectonics we are little nearer to understanding the process or processes at depth by which they are initiated and maintained. Thermal convection in some form is probably the only mechanism capable of supplying the energy requirements, although convection in this context should be interpreted in its broadest terms, that is, as the generation of horizontal temperature gradients which result in gravitational instabilities and thus vertical transport of hot and cold material³⁶. Plate tectonics, however, make it clear that there can be no simple relationship between mantle convection currents and surface features, as Hess envisaged. The cold descending slab of oceanic lithosphere landward of the trench systems is clearly a source of gravitational energy and convection as I have defined. That such a "sinker" exists and is an important driving force is reflected in the tensile nature of intermediate focus earthquakes beneath certain trench systems³⁷.

Present knowledge of the physical properties of the Earth's mantle is far from perfect, particularly with regard to temperature and viscosity, two all-important parameters; but it seems probable that convection is only possible in that part of the upper mantle which is nearest to its melting point. This region, sometimes termed the "asthenosphere", is thought to be between depths of approximately 70 and 400 km, the latter depth being particularly uncertain. Convection in this shell would produce two further effects: a net viscous drag on the lithospheric plates above and, as a result of thermal upwelling at ridge crests and the resultant elevation of ridges, the flanking plates are situated in gravity potential gradients which tend to pull them downhill³⁸.

There is therefore no lack of possible driving mechanisms: plates may be pushed apart by mantle upwelling, pulled apart by sinkers beneath the trench system, carried by convection currents in the asthenosphere or slide under the influence of gravity. Moreover, stresses set up between and within plates may in part determine their motions; this may be particularly relevant in the case of small plates. It seems probable that plate movements are not solely attributable to any one of these effects but result from a combination of all of them acting in varying degrees on individual plates.

More than fifty years ago Taylor and Wegener formulated the concept of continental drift within the more respect-

able and plausible geological framework of uniformitarianism, rather than catastrophism. Most geologists, however, rejected the hypothesis on the grounds that the geological evidence was equivocal and because geophysicists maintained that there was no plausible mechanism to account for drift. Surprisingly, with the advent of compelling evidence for sea floor spreading in the mid-1960s, geophysicists, both theoretical and applied, were the first to accept the new findings and review their implications for their own areas of interest. Thus the wave of activity and re-interpretation which had been initiated in the area of marine geology and geophysics spread out and through seismology and all areas of theoretical and applied geophysics. Only within the past year or two has this excitement reached the classical areas of geology relating to structure, magmatism, sedimentation and metamorphism. Symptomatic of this was the seance held under the auspices of the Geological Society of America at Asilomar, California, during December last. Here a limited number of invited geologists met to discuss "the meaning of the new global tectonics for magmatism, sedimentation and metamorphism in orogenic belts"³⁹. Illustrative of the concepts discussed at this conference are the re-interpretations of Dewey⁴⁰ and Moores⁴¹ of the Appalachian/Caledonian and western Cordillera Orogens respectively. Many of the basic tenets of these new syntheses were advanced many years ago by, for example, Takeuchi and Uyeda⁴² in recognizing the possibility of present day regional metamorphism in the Japanese Island Arc; by Hess⁴³ in postulating that ultramafic bodies in mountain belts were emplaced in the initial stages of orogeny, and, perhaps most significantly, by Hess again in stating in 1940 (ref. 44) that "perhaps no greater misconception exists in geology than that geosynclines localize mountain building".

Lunar Samples

The study of lunar samples returned to Earth by Apollo missions 11 and 12 has enabled us not only to gain insight into the history and composition of the Moon, but also to see the history of the Earth and some of its geochemical peculiarities in a new and refreshing light. Of the initial results⁴⁵ the great age of the lunar maria came as a surprise to many, as did the occurrence of anorthosite fragments in the lunar "soil". The discovery that anorthosite (an essentially mono-mineralic calcium-aluminium-silicate rock) is an important rock type on the Moon and may well constitute the lunar highlands⁴⁶ illustrates the way in which the study of lunar materials has heightened interest and added a new dimension to the study of similar materials on the Earth. Anorthosites occur terrestrially but present something of a geological enigma in that their distribution is limited in space and time. On a pre-drift reconstruction of the northern and southern continents anorthosite outcrops plot in two belts, one striking south-west-north-east across North America and extending into Scandinavia, and the other crossing Africa, Madagascar and India. All these anorthosites yield radiogenic ages within the range 1,100 to 1,700 million years⁴⁷. Terrestrial anorthosites are thought to form in conditions of high pressure and temperature, probably at the base of tectonically thickened continental crust⁴⁸; to add to the enigma they occur in orogenic belts, such as the Grenville of North America, which are devoid of Hess's "Alpine-type" ultramafics. The full significance of the occurrence of anorthosite on the Earth and Moon is still not understood and poses an intriguing problem for

the future. The recent publication of a collection of research papers on the terrestrial anorthosite problem is timely, if fortuitous⁴⁸.

After a year of intensive study of the lunar rock samples Schreiber and Anderson⁴⁹ provided a little light relief in noting that the velocity of sound in lunar rocks is comparable with that in terrestrial cheeses. Cheeses, however, obey the velocity-density relations proposed for Earth rocks, whereas lunar rocks deviate widely from them because of their high porosities.

For many years the Earth sciences were the poor sister of the physical sciences. Ironically, at a time when most other fields in this area are suffering a "recession" and having difficulty in placing their newly graduated PhDs, the geosciences are enjoying a revolution in thinking within their traditional areas of study and facing new frontiers as a result of the space programme and heightened activity in the study of the ocean basins and the physical environment as a whole.

Highlights of High Energy Physics

by

RICHARD WILSON

Cyclotron Laboratory,
Harvard University,
Cambridge, Massachusetts 02138

Data provided by accelerators in various parts of the world have given high energy physicists plenty to think about during the past year.

In late 1967 the 70 GeV proton synchrotron at Serpukhov in the USSR began operation, just in time for the fiftieth anniversary of the October revolution. This is presently the accelerator of the highest energy in the world, and during the past year the first experiments have been reported from Serpukhov¹⁻⁵. They have been performed by a joint group from CERN and the USSR, using a negative particle beam, bending outward from an internal target; a positive particle beam must await the extraction of the proton beam; high energy positive particles at 0° from an internal target will bend inward further into the machine.

The first experiments have been measurements of total cross sections for three negative particles π^- , κ^- , \bar{P} ; on hydrogen, deuterium, and nine elements up to uranium, at energies of 20–65 GeV. The excitement in these cross sections arises from Pomeranchuk's conjectures⁶, often dignified by the name theorem, that the total cross sections of any particle on a nucleon become independent of energy at high energies, and that the cross section of a particle becomes equal to that of its antiparticle.

Earlier experiments at Brookhaven⁷ and CERN had shown a steadily decreasing cross section in most cases, as shown for π mesons in Fig. 1. The cross sections for π^+P and π^-P collisions were still 5 per cent apart at 20 GeV, and it is not certain whether they were extrapolating to the same value; a simple plot $\sigma = A + B/E^{1/2}$ (Fig. 2) showed a slight difference, but more complex extrapolations could be made where the difference in cross sections vanished at infinite energy as Pomeranchuk suggested. One of these, by Barger⁸, is shown as a solid line in Fig. 1.

Surprising Cross Sections

The new data apply to negative particles only; however, the π^+P cross section should equal the π^-N cross section because these states have the same isotopic spin and the charge independence of the nuclear forces makes the cross sections equal. The π^-N cross section is obtained from the π^-D cross section by subtracting the π^-P cross section and making a small correction for the shadowing of one nucleon by the other. These data are also plotted in Figs. 1 and 2. It is obvious that the earlier expectations are much changed; the cross sections are flattening off much faster than any simple formula can describe; and the two cross sections are not approaching each other. The result of the excessively

rapid flattening of the cross section also holds for $\bar{P}P$, $\bar{P}N$, κ^-P and κ^-N cross sections, though here it is not possible to compare particle and antiparticle cross sections until a positive particle beam is available; the charge independence argument possible for π^-N and π^+P cross sections does not work for these combinations.

These new data have led to a flurry of theoretical activity. While it was believed that cross sections obeyed the Pomeranchuk "theorem" at high enough energies, the interest in the total cross sections at high energies

Fig. 1. Total cross sections for particles on protons and neutrons. Solid lines are fits* to old data. The fits extrapolate, as $E \rightarrow \infty$, 4 mb (PP), 33 mb ($\pi^\pm N$), and 25 mb ($K^\pm P$).

waned; it seemed that this branch of high energy physics was complete. Now there are several new ideas. One of them⁹, based on a complex application of field theory, suggests that the cross sections increase with energy logarithmically; but that particle and antiparticle cross sections have, at high energies, a constant difference. This increase of cross section should, in this model, be accompanied by many low energy π mesons, produced at large impact parameter. The word "pionization" has been used to describe this process. This theory therefore makes a prediction (a phenomenon all too rare in high energy physics) that these low energy pions will be found in high energy collisions, and in increasing number as the energy increases.

Fig. 2. π^-P and π^+P ($=\pi^+N$) total cross sections plotted against $E^{-1/2}$ to display clearly the discontinuity. \bullet , Foley *et al.* (AGS); \circ , Allaby *et al.* (IHEP).

Results are eagerly awaited from the positive particle beam at Serpukhov which should be available in the next two years; this should confirm the $\pi^\pm P$ behaviour for π^\pm and P^\pm . Also in two years, the 30 GeV intersecting storage rings (ISR) at CERN, and the 200–500 GeV accelerator at the National Accelerator Laboratory, Batavia, should be working. It may be possible to see the cross sections turn upwards; even more important, pionization, if it occurs, should be directly measurable at these energies.

Electron-Positron Interactions

The operation of the electron-positron storage ring (ADONE) at Frascati was described last year in *Nature*¹⁰. The experimental programme was set back by a four month strike, but preliminary results were presented to the recent international conference on high energy physics at Kiev (from groups led by M. Conversi, G. Salvini, V. Silvestrini and A. Zichini).

Fig. 3. Typical Feynmann diagrams showing the sensitivity to different propagators. (a) Space-like photon propagator $q^2 = 4E^2 \sin^2\theta/2$; (b) time-like photon propagator $q^2 = -4E^2$; (c) space-like electron propagator $q^2 = 4E^2 \sin^2\theta$.

Technical difficulties restricted the first operation to energies (E) of 800 to 1,000 MeV in each beam, making a total energy ($2E$) of 1,600 MeV to 2,000 MeV in the centre of mass. It was originally intended to keep the electron and positron beams apart by an electrostatic field and to make them meet and cross at an angle in each interaction region; the length of the interaction region would be limited thereby. For reasons not yet fully understood, this led to instabilities. Accordingly the beams are not kept apart, but interact whenever one radio frequency "bunch" meets another—at six places of 30 cm length around the machine. Around four of these interaction regions experimental equipment is placed, and four experiments proceed simultaneously for sixteen hours a day. The most exciting result to come from these measurements is a large cross section for producing hadrons—presumed to be mostly π mesons. The electron and positron annihilate; the subsequent interaction with hadrons is described by a virtual photon which is time-like. We can produce all known charged particles in pairs, $\mu^+\mu^-$, e^+e^- , $\pi^+\pi^-$ and so on. This is done without any intermediate hadron state. It is a very clean way of studying specific hadron properties, similar to the study of proton sizes by electron scattering.

Spark chambers are set up on either side of the interaction region, and in a typical case they are triggered whenever two charged particles are observed on opposite sides, which pass through two counters each. There are many more events due to cosmic ray events than due to the beam-beam interactions, but when the tracks are examined in detail, we pick those that come from the interaction region, and those which are in time with the interaction (which can be measured from the phase of the radio frequency). These restrictions reduce the cosmic ray background to manageable proportions. The μ mesons are identified by the fact that they penetrate a lot of absorber; electrons by the fact that they produce showers in lead absorber, and hadrons by the

fact that they produce a single track with no showers, and do not penetrate as much absorber as muons.

Pairs of particles will always be produced collinear, for the centre of mass system and the laboratory system coincide. More than 5,000 electron-positron pairs and μ pairs have been so identified. About fifteen hadron pairs are also seen, but some of these can be confused with electron pairs which fail to shower. So far we can say that the π meson form factor lies between the point form factor and the rho dominance form factor.

But when three or more hadrons are produced they are easily recognized because the tracks are not collinear. Sometimes two non-collinear tracks are observed; sometimes three and four, and in one case, five tracks. Since the solid angle subtended by the detector systems is small, $1/4$ of 4π , this implies a large average multiplicity ($7-1/2$) of the interaction. This already is surprising; with an average centre of mass energy of 1,800 MeV this leaves only 240 MeV per particle; only 100 MeV more than the rest mass of a pion!

The total cross section can be estimated; it turns out to be five times greater than that for pion pairs with point pions. Within the limited range it seems independent of energy.

Often general relationships relate one cross section with another; Regge pole theory relates high energy cross sections with low energy particle states of different angular momentum; current algebra has related the low energy production of pions with a sum over high energy cross sections. No such relationship exists here, however. Early in the development of current algebra it was thought that the commutator between two electromagnetic currents $[j_\mu(x), j_\nu(0)] = 0$. Schwinger showed that this commutator is indeterminate and, further, that this commutator equals the cross section for an electron and a positron to produce a hadron. These terms, promptly dubbed "Schwinger terms", cannot therefore be predicted from previous experiments.

Various models can be made to aid anyone who wishes to speculate; the particles might all behave like pions; because the number of possible particle pairs increases with energy, the total cross section would then become large. Or they could have form factors with the cross sections reduced by the square of the form factors $[F(q^2)]^2 = [F(4E^2)]$. The usual guesses were a "vector dominance" form factor

$$F(q^2) = \frac{m_e^2}{m_e^2 + q^2} [q^2 = -4E^2]$$

with $m_e^2 \simeq 0.55$ (GeV) and where it was assumed that the hadron interacts only through the intermediary of a rho meson. This might work for the pion (and indeed it fits in detail the production of rho mesons). For the proton, however, this form factor should also fit electron-proton scattering experiments where, by contrast, it is found experimentally that

$$F(q^2) \simeq \left[\frac{0.71}{0.71 + q^2} \right]^2$$

At $q^2 = -4$ GeV² these are $1/7$ and $1/20$ respectively and the cross sections $1/49$ and $1/400$. For the total cross sections, into all possible hadronic states, various speculations have been made that this total cross section equals that for a point pion; increases as E^2 , or decreases as E^2 . Experiment is now beginning to settle these questions.

These results show that there is a wealth of new information to be gained from high energy colliding beams. New devices at Novosibirsk, CEA, DESY and SLAC are expected to join in this investigation within the next few years.

Quantum Electrodynamics

Quantum electrodynamics (QED) is quantitatively the most successful physical theory. For example, experiments on the Lamb shift now agree with theory to within the experimental error of 1.0 MHz; this can be compared with the $^2p_{1/2} - ^2s_{1/2}$ transition frequency of 1,000 MHz, the $^2p_{3/2} - ^2s_{1/2}$ transition of 9,000 MHz or the $^2p - ^1s$ transition of 10^9 MHz. The precision is fantastic.

The theory has within it, however, the seeds of its own destruction; it seems to be fundamentally divergent at small distances (large momentum transfers). This is the domain of the high energy physicist and there is an incessant search for such deviations. The procedure is to measure some process which can be calculated by QED. Any deviation is expressed as a modification of an appropriate propagator in the Feynmann diagram

$$1/q^2 \rightarrow 1/q^2 + \frac{1}{q^2 + \Lambda^2}$$

Such a modification can be due to a heavy photon of mass Λ . Lee and Wick¹¹ particularly emphasize the importance of this.

The new colliding beam measurements at Frascati give the latest and cleanest tests of the theory; the production of electron-positron pairs, μ pairs and γ pairs are sensitive respectively to modifications of the space-like photon propagator, a time-like photon propagator, and a space-like electron propagator. In each case they find $\Lambda > 3$ GeV. The only comparable measurement is the two year old measurement of the anomalous moment of the muon ($g-2$) at CERN where the finding for a time-like photon propagator is $\Lambda > 5$ GeV.

At one time it was hoped that strong interactions could give a deviation giving Λ somewhere close to the nucleon mass; no one knows where to look for such a deviation now; the divergences do not become serious until we reach energies of e^{137} electron masses which is much larger than presently conceived accelerators!

Rous Sarcoma Virus: a Function required for the Maintenance of the Transformed State

by

G. S. MARTIN

Virus Laboratory,
University of California,
Berkeley,
California 94720

A temperature sensitive RNA tumour virus mutant has been isolated whose properties indicate that part of the viral genome is required for transformation but not for growth.

It now seems likely that the genome of DNA or RNA-containing tumour viruses persists in cells transformed by them, at least in most cases and perhaps in all. In the case of DNA tumour viruses the presence of viral DNA can be demonstrated by DNA-RNA hybridization or by the production of infectious virus following fusion with cells which allow virus growth (for reviews, see refs. 1 and 2). Cells transformed by RNA tumour viruses may release infectious virus while continuing to divide³⁻⁶, for these viruses, unlike the DNA tumour viruses, are not cytotoxic. In certain situations, depending mainly on the type of cell and virus strain used, non-infectious particles are released which can be detected by electron microscopy or by labelling with radioactive precursors^{7,8}. Even in those cases where no particles are detectable, the genome can frequently be rescued by co-cultivation or fusion with permissive cells⁸⁻¹⁰.

The role of viral genes in producing the characteristic physiological changes of transformation is, however, still unclear. In the case of the DNA tumour viruses it is not yet known whether the continued expression of viral genes is required to maintain the transformed state^{1,2}. A considerable number of temperature-sensitive mutants of polyoma have been isolated¹¹⁻¹³, but none of the mutants so far described is defective in the ability to stimulate DNA synthesis in confluent cells, to produce abortive transformation, or to maintain the transformed state¹¹⁻¹⁵. In the case of the RNA tumour viruses, on the other hand, a specific role for viral genes in transformation is suggested by comparison of the leukosis and sarcoma viruses. These viruses, which are structurally and chemically indistinguishable¹⁶, grow in fibroblast cultures but only the sarcoma viruses transform them. Goldé¹⁷ and K. Toyoshima, R. R. Fris and P. K. Vogt (manuscript in preparation) have recently shown that irradiation of certain strains of avian sarcoma virus results in the formation of viruses which retain the ability to grow but are no longer able to transform. These experiments indicate that part of the genome of RNA tumour viruses is required for transformation but not for growth. I now describe the isolation of a temperature-sensitive mutant of the Schmidt-Ruppin strain of Rous sarcoma virus the properties of which indicate that the mutation affects a function required for the maintenance of the transformed state but not for the growth of the virus.

Isolation of the Mutant

The methods used for the growth and assay of virus stocks were those previously described¹⁸, except that the agar overlay used in the assay was supplemented with 3 mg/ml. glucose and an extra 4 ml. of agar overlay was added after 4 days incubation. C/O or C/B (ref. 19) chick fibroblasts were used throughout. The method used to clone virus stocks involved picking clones of transformed cells growing in agar suspension: transformed cells grow into large colonies in agar suspension whereas normal cells either do not divide or form only small colonies^{20,21}. Cells were plated at 1.5×10^6 per 10 cm plastic dish (Falcon Plastics) in medium 199 (Grand Island Biological Co.) containing 2 per cent tryptose phosphate broth

(TPB, Difco) and 1 per cent calf serum (Microbiological Associates). The next day the medium was removed and the cells were infected with 0.5 ml. of a virus stock diluted to between 2 and 20 focus forming units (f.f.u.) per ml. After 1 h adsorption the cells were trypsinized and re-suspended at 1.5×10^6 per ml. in medium 199 or Scherer's medium containing 10 per cent TPB, 4 per cent calf serum, and 1 per cent chicken serum (Microbiological Associates; heat inactivated for 60-90 min at 60° C). 0.5 ml. of this cell suspension was then added to 1 ml. of the same medium containing 0.6 per cent agar and poured over 5 ml. base layers of the same agar mix. (The transformed clones tend to grow faster in medium 199 than in Scherer's but are less readily distinguished from the small clones of normal cells which also grow to a greater extent in medium 199.) After incubation for about a week at 38°-39° C or 2 weeks at 36° C clones were picked onto growing monolayers of cells, using 2 μ l. capillaries (Drummond Microcaps) or drawn-out Pasteur pipettes. The cells were then grown and transferred when necessary until extensive transformation was obtained.

A stock of Schmidt-Ruppin virus, SR-RSV-A, free of avian leukosis viruses, was kindly provided by Dr W. Levinson, who had previously obtained the virus from Dr P. K. Vogt. The virus was recloned by the method described above. The recloned Schmidt-Ruppin virus did not plate on RAV1-infected or C/A cells, and chicken antisera prepared against it neutralized RSV(RAV1) but not RSV(RAV2), confirming that this virus belongs to the A subgroup^{19,22,23} of avian tumour viruses. It has been reported²⁴⁻²⁷ that the Schmidt-Ruppin strain, unlike the Bryan strain, is not "defective", in the sense that no helper virus is required for the production of virus infectious for the commonly used C/O or C/B type fibroblasts. Stocks of the Schmidt-Ruppin strain can be prepared in which leukosis viruses are not detectable by endpoint dilution procedures²⁴⁻²⁷; infection at low multiplicities results in the formation of foci^{24,25,27} or pocks on the chorio-allantoic membrane²⁶ which all release infectious virus. To confirm that cells singly infected by SR-RSV-A release infectious progeny, cells were infected at a multiplicity of about 10^{-5} with SR-RSV-A and also with the helper-dependent Bryan strain, RSV(RAV1). The infected cells were plated in agar suspension and clones picked as described. As expected, all SR-RSV-A infected clones released infectious virus (6 out of 6 in one experiment, 20/20 in another) whereas most of the Bryan clones (5/6) did not.

To isolate mutants of the virus, the mutagen N-methyl-N'-nitro-N-nitrosoguanidine ("nitrosoguanidine", MNNG) was used: this mutagen has been shown by Hanafusa²⁸ to lead to the production of mutants of Bryan RSV β (0) which are unable to yield progeny infectious for quail cells. A crude stock of SR-RSV-A, titre about 10^6 f.f.u./ml., was mixed with an equal volume of 0.2 M phosphate buffer (pH 6.0) containing 0.002 M EDTA and 2 mg/ml. MNNG (Aldrich Chemical Co., dissolved at 100 mg/ml. in dimethylsulphoxide immediately before use). After 10 min incubation at 30° C the mixture was chilled and dialysed extensively against standard buffer (0.1 M

Fig. 1. Growth of SR-RSV-A and T1 at 41° C and at 36° C. Cells were seeded in four bottles (5×10^5 cells per bottle in medium 199 containing 2 per cent TPB and 1 per cent calf serum) and infected after 24 h with $2-4 \times 10^4$ f.f.u. of either SR-RSV-A or T1. After the virus had adsorbed for 1 h, the cells were washed and the medium was changed to medium 199 plus 10 per cent TPB and 5 per cent calf serum. One bottle of each pair was held at 36° C, the other at 41° C, and the medium was changed every 24 h. After 4 days the cultures kept at 36° C were partially transformed, the SR-RSV-A-infected culture at 41° C was completely transformed, whereas the T1-infected cells at 41° C showed no transformation. The virus in the medium collected each day was titrated at 36° C. The virus yield is expressed as the amount of virus in 5 ml. medium divided by the amount of virus used to infect the cells (2.1×10^4 f.f.u. of SR-RSV-A; 3.4×10^4 f.f.u. of T1). △, SR-RSV-A at 41° C; ▲, SR-RSV-A at 36° C; ○, T1 at 41° C; ●, T1 at 36° C.

NaCl-0.01 M Tris-HCl (pH 7.6)-0.001 M EDTA). The titre of the mutagenized stock was approximately 5×10^2 f.f.u./ml., representing a survival of about 10^{-3} compared with a control without nitrosoguanidine. The surviving viruses were cloned at 35°-36° C using the agar suspension method described. Two hundred and sixty clones were picked and the resulting virus stocks, grown at 35°-36° C, were tested for their ability to produce foci at 36° C and 41° C. Six were found to be unable to produce foci at 41° C; one of these mutants, T1, was re-cloned, and the properties of this mutant will be described. Because the permissive and non-permissive temperatures are only 5° C apart the characterization of this mutant was carried out using cultures grown in sealed 25 cm³ plastic bottles (Falcon Plastics) immersed in water baths controlled to an accuracy of $\pm 0.05^\circ$ C by mercury contact thermoregulators.

Growth of the Mutant at the Non-permissive Temperature

The ability of the mutant to grow at the non-permissive temperature was tested as recorded in Fig. 1. There is no significant difference between the wild type and the mutant in the rate of accumulation of virus either at 41° C or at 36° C. Because Rous sarcoma virus is thermally inactivated at a significant rate, the amount of infectious virus in the medium depends not only on the rate of production but also on the rate of inactivation³. The rates of inactivation at 41° C of the wild type and of the mutant (grown at 41° C) were therefore measured. The survival of the wild type after 2 h was 46 per cent and after 4 h, 22 per cent; that of the mutant after 2 h was 44 per cent and after 4 h, 19 per cent. At 41° C there is no significant difference between the mutant and the wild type either in the rate of accumulation of virus or in the rate of inactivation, so that it may be concluded

Table 1. SUPERINFECTION OF T1-INFECTED CELLS GROWN AT 41° C

Superinfecting virus	No. of infected cells (per 100 mm plate) capable of forming foci at 41° C	
	Uninfected cells	T1-infected cells
None	0	4.0×10^2
SR-RSV-A	1.4×10^5	4.2×10^2
RSV(RAV1)	1.5×10^5	6.5×10^2
PR-RSV-C	1.8×10^4	2.8×10^4

Cells were infected with T1 at a multiplicity of infection of about 10^{-2} f.f.u./cell and these and a parallel culture of uninfected cells were grown at 41° C for 7 days with one transfer. Infected and uninfected cells were then plated at 1.5×10^5 /100 mm plate and after a day at 41° C a second infection was carried out with $2-10 \times 10^4$ f.f.u. of either SR-RSV-A, RSV(RAV1), or PR-RSV-C (Prague virus, a C group sarcoma virus kindly provided by Dr P. K. Vogt). After the virus had adsorbed for 1 h, the cells were washed with Tris-saline and then exposed to 0.05 M glycine-HCl buffer (pH 2.2) for 60 s, to inactivate adsorbed but unpenetrated virus²². After restoring the pH to neutrality with three washes of Tris-saline, the cells were incubated for 2 h in medium. The cells were then trypsinized and plated at various dilutions on sensitive cells to determine the number of infected cells capable of forming foci at 41° C; anti-SR-RSV-A antibody was added to the medium of the assay plates to reduce the background arising from the spread (before the agar overlay) of temperature-resistant revertants of T1.

that the mutation does not affect the growth of the virus. The mutant grown at 41° C was not able to form foci on subsequent plating at 41° C, indicating that the defect is not altered by growth at the non-permissive temperature.

At 41° C the behaviour of this mutant is similar to that of the avian leukosis viruses, which grow in fibroblast cultures without transforming them. Cells infected by an avian leukosis virus are in general resistant to superinfection by viruses of the same subgroup²¹, probably because of the blocking of receptors required for viral penetration. To determine if cells infected by the mutant also exhibit this subgroup-specific interference the experiments documented in Table 1 were performed. As expected, the T1-infected cells are resistant to superinfection by the A group viruses, RSV(RAV1) and SR-RSV-A, but not to infection by PR-RSV-C. The high degree of resistance to A group viruses indicates that almost all the cells are infected.

Effect of Mutation on Ability to Transform

The mutant grows at 41° C without producing any visible effect on the morphology of the infected cells. If the function which is defective at 41° C is required only to initiate the transformed state, it would be expected that T1-transformed cells growing at the permissive temperature would remain transformed when shifted to the non-permissive temperature. It was found, however, that T1-transformed cells when shifted to 41° C rapidly lost their rounded refractile appearance and assumed a normal or near-normal appearance, the change being largely complete within 4 h; cells infected by the wild type were not affected by the shift. This indicates that the mutant function is required to maintain the morphological alterations which are characteristic of the transformed state. The reverse change, from the normal to the transformed morphology, occurs when a T1-infected culture grown at 41° C until completely infected (as judged by the resistance of the cell population to superinfection) is shifted down from 41° C to 36° C. This change is slow, however, taking about 2 days; presumably this is at least in part because cellular metabolism is slow at the permissive temperature.

The effect of the mutation on the ability of the infected cells to grow in agar suspension was also investigated (Table 2). It can be seen that T1-infected cells do not form transformed clones at 41° C. Moreover, even if grown at 37° C for 4 days, they are unable to grow into recognizable transformed clones when shifted to 41° C. T1-infected cells maintained at 41° C for 4 days can, however, produce transformed clones when shifted down to 37° C. In a similar experiment, infected cells in agar suspension were shifted to 41° C after 9 days' growth at 37° C, by which time the transformed clones were clearly distinguishable. After incubation for a further 6 days, it was clear by inspection that clones produced by T1 after incubation for 15 days at 37° C were larger

Table 2. EFFECT OF TEMPERATURE ON THE GROWTH IN AGAR SUSPENSION OF CELLS INFECTED WITH SR-RSV-A OR T1

Temperature of incubation	No. of transformed clones per bottle	
	SR-RSV-A	T1
41° C for 16 days	310, 330	0, 0
37° C for 16 days	210, 222	209, 204
37° C for 4 days; then 41° C for 12 days	274, 270	0, 0
41° C for 4 days; then 37° C for 12 days	233, 220	197, 174

A preliminary experiment indicated that the optimum permissive temperature for the growth of T1-infected cells in agar suspension was 37° C, and that at this temperature the transformed clones become distinguishable from the small clones of normal cells after incubation for 5–6 days. Cells were therefore infected with SR-RSV-A or T1 (about 1,000 f.f.u. per 1.5×10^6 cells), suspended in Scherer's agar as described, and kept at either 37° C or 41° C. After 4 days, just before the transformed clones had become distinguishable some bottles were shifted from one temperature to the other. The number of transformed clones was counted after 16 days.

than those shifted to 41° C after 9 days. These results indicate that the mutant function is required to maintain growth in agar suspension.

Genes for Growth and Transformation

The properties of this mutant indicate that part of the viral genome is required for transformation but not for growth, because only transformation is affected at the non-permissive temperature. This is in agreement with the conclusions of Goldé¹⁷ and of Toyoshima *et al.*, who have shown that irradiation of avian sarcoma viruses by γ -rays or ultraviolet light leads to the production of non-transforming mutants which are able to grow as well as (or better than¹⁷) the wild type. Goldé (ref. 17 and personal communication) has proposed that the part of the genome which codes for the oncogenic functions includes information for the synthesis of an inhibitor of viral multiplication. The properties of T1 neither support nor contradict this proposal, but if such an inhibitor exists, the mutation in T1 cannot affect it, for the mutant grows at the same rate as the wild type at both permissive and non-permissive temperatures (Fig. 1).

Macpherson³⁰ has observed that BHK21 cells transformed by the Schmidt-Ruppin strain (presumably SR-RSV-D, see ref. 31) can give rise to non-transformed cells from which an active transforming genome cannot be rescued by injection into chickens. He suggested that this reversion arose from the loss or inactivation of the viral genome. It would follow that the presence or expression of viral genes is required to maintain the transformed state. This conclusion, in particular the idea that the expression of viral genes is required to maintain transformation, is supported by the properties of temperature sensitive mutants of avian sarcoma viruses which are unable to sustain transformation when the infected cells are transferred to the high temperature.

These mutants include the mutant described here and the mutants of B77 recently isolated by Toyoshima and Vogt³², which differ from T1 in that they are unable either to grow or to transform at the non-permissive temperature.

Further characterization of these and other mutants may help in identifying the biochemical changes in infected cells which are involved in transformation.

I thank Dr H. Rubin, in whose laboratory this work was carried out, for advice and discussion; P. H. Duesberg, T. Gurney, H. Fraenkel-Conrat, G. R. Martin and M. Weber for suggestions and criticism; P. K. Vogt and B. R. Burmester for providing C/A cells; and Mildred Hughes for technical assistance. This work was supported by a fellowship from the Jane Coffin Childs Fund for Medical Research; and a US Public Health Service research grant (to Dr Rubin) from the US National Cancer Institute.

Presence of DNA in Rous Sarcoma Virus

by

WARREN LEVINSON

University of California,
San Francisco 94122

DNA has been isolated from the virion of Rous sarcoma virus. It consists of two components which seem to correspond to the two species of DNA synthesized *in vitro* by the recently identified virion RNA-dependent DNA polymerase.

It is widely believed that cells transformed with Rous sarcoma virus (RSV) contain a DNA transcript of the viral RNA, the so called "provirus"¹. In spite of ample evidence that the bulk of the nucleic acid is RNA^{2,3}, it therefore seemed worthwhile to investigate the possibility that some DNA is enclosed within the virion, especially

now that RSV has been shown to contain an RNA-dependent DNA polymerase (refs. 4, 5 and J. M. Bishop *et al.*, manuscript in preparation).

Purified RSV (Schmidt-Ruppin strain) was doubly labelled with ³H-thymidine and ¹⁴C-uridine and analysed on sucrose gradients using both isopycnic (Fig. 1A) and

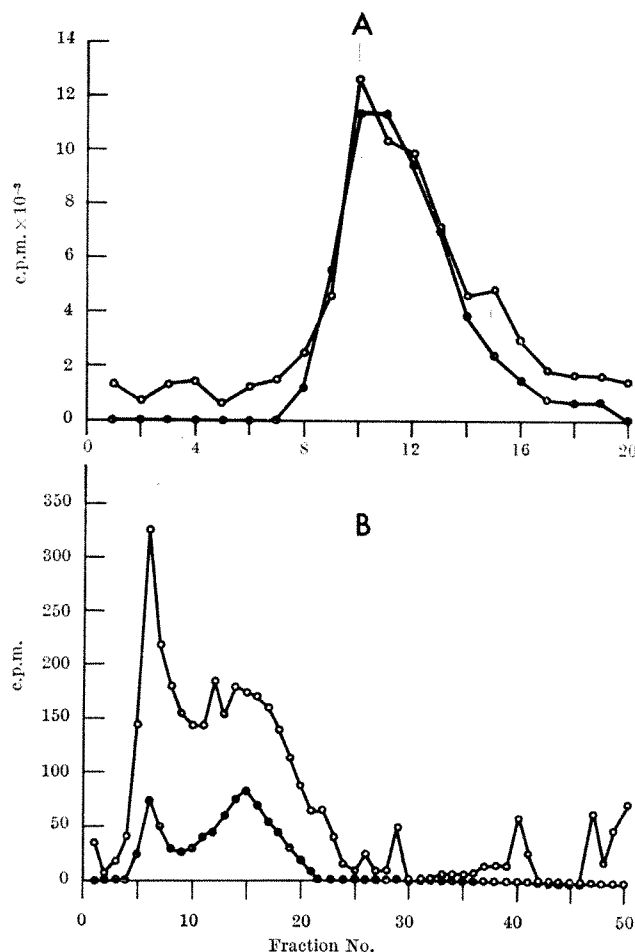

Fig. 1. Sucrose gradient analysis of RSV labelled with ^3H -thymidine and ^{14}C -uridine. RSV-infected chick embryo cells were exposed in culture to $50 \mu\text{Ci/ml}$ ^3H -thymidine (specific activity 20 Ci/mmol) and $0.1 \mu\text{Ci/ml}$ ^{14}C -uridine (50 mCi/mmol) overnight. The tissue culture conditions and purification of RSV were performed as described in Bishop *et al.*³. A, Isopycnic centrifugation in a 25–65 per cent sucrose gradient at 25,000 r.p.m. for 16 h at 4°C in a Spinco '25'3' rotor. B, Rate zonal centrifugation in a 15–30 per cent sucrose gradient with a 65 per cent sucrose cushion at 40,000 r.p.m. for 40 min at 4°C in a Spinco 'SW 41' rotor. Gradient fractions were collected and counted as described in Bishop *et al.*³. \circ , ^3H -thymidine; \bullet , ^{14}C -uridine.

rate zonal (Fig. 1B) centrifugation. Materials labelled with ^3H -thymidine and ^{14}C -uridine were found to sediment together. Biological activity as determined by the focus forming assay coincides with the peaks of radioactivity. Much of the rapidly sedimenting virus which reaches the 65 per cent sucrose cushion represents aggregates of RSV. The more slowly sedimenting peak has the rather broad distribution typical of RSV in rate zonal sucrose gradients. Biological activity again coincided with peaks of radioactivity. Subsequent experiments revealed that the Bryan high titre strain of RSV also incorporates ^3H -thymidine into the virion.

The RSV-associated thymidine was further studied by extracting the nucleic acid of the ^3H -thymidine labelled RSV according to the procedure of Bishop *et al.*³ and treating with deoxyribonuclease, ribonuclease and 1 M NaOH. The data in Table 1 indicate that the ^3H -thymidine labelled nucleic acid is sensitive to deoxyribonuclease but not to ribonuclease or 1 M NaOH. It seems likely therefore that the thymidine is contained in DNA rather than, for example, in transfer RNA. Because it is the methyl group of the thymidine that is labelled, the incorporation cannot be the result of demethylation and subsequent incorporation of uridine.

Could this putative piece of DNA be an artefact from the adsorption of cellular DNA onto the surface of the

Table 1. EFFECT OF NUCLEASES AND NaOH ON ^3H -THYMIDINE LABELLED NUCLEIC ACID FROM RSV

Treatment	^3H -Thymidine (c.p.m.)	Percentage degraded
None	2,651	
Deoxyribonuclease	734	72
None	2,734	
Ribonuclease	2,232	18
None	2,860	
NaOH	2,325	19

^3H -thymidine-labelled nucleic acid from RSV was prepared according to the procedures described in Fig. 2 and treated as follows: deoxyribonuclease (ribonuclease-free), $20 \mu\text{g/ml}$ in 0.01 M NaCl– 0.01 M Tris–HCl ($\text{pH } 7.4$)– 0.01 M MgCl_2 ; ribonuclease (boiled) $25 \mu\text{g/ml}$ in 0.01 M NaCl– 0.01 M Tris–HCl ($\text{pH } 7.4$)– 1 M NaOH. All preparations were incubated at 37°C for 1 h then precipitated with 10 per cent trichloroacetic acid and counted as described in Bishop *et al.*³.

virion? We tested this possibility in two ways. First, two reconstruction experiments were performed; one in which ^3H -thymidine-labelled uninfected chick embryo cells were sonicated and the sonicate was mixed with unlabelled RSV, and the other in which the growth medium from ^3H -thymidine-labelled uninfected chick embryo cells was mixed with unlabelled RSV. The mixtures were then purified according to the modification of the Duesberg procedure for RSV used in this laboratory³. No ^3H -thymidine counts were associated with the purified RSV in either preparation. The second set of experiments was designed to determine the constancy of the ratios of ^3H -thymidine to ^{14}C -uridine to focus forming units in different purified preparations. There is good correlation of the three parameters among the RSV preparations (Table 2). It therefore seems unlikely that the ^3H -thymidine in RSV is associated non-specifically.

Fig. 2. Sucrose gradient analysis of ^3H -thymidine labelled nucleic acid from RSV. Labelled RSV was prepared by exposing infected cultures to $50 \mu\text{Ci/ml}$ ^3H -thymidine overnight. Similar cultures were exposed to $100 \mu\text{Ci/ml}$ $\text{H}_3^{32}\text{PO}_4$ overnight. The tissue culture conditions, purification of the RSV and extraction of the nucleic acid were as described in Bishop *et al.*³. A mixture of the ^3H -thymidine-labelled nucleic acid and the ^{32}P -labelled marker nucleic acid was centrifuged on a 15–30 per cent sucrose gradient at 60,000 r.p.m. for 75 min in the Spinco 'SW 65' rotor. Gradient fractions were collected and counted as described in Bishop *et al.*³. \circ , ^3H -thymidine; \bullet , ^{32}P .

From the data in Table 2, the estimated ratio of the number of thymidine:uridine molecules in the virion is 1:200. This value is at variance with the data of Robinson² which suggest that the amount of ^{32}P -labelled DNA in the nucleic acid recovered from RSV is less than 1 part in 2,000.

Experiments were then performed to characterize the RSV-associated DNA. To determine whether it was

Table 2. RELATIONSHIP OF ³H-THYMIDINE, ¹⁴C-URIDINE AND INFECTIVITY IN RSV PREPARATIONS

	¹⁴ C-U	c.p.m. ³ H-T	Infectivity (i.f.u.)	³ H/f.f.u.	Ratios ³ H/ ¹⁴ C	¹⁴ C/f.f.u.
I	404	188	2.7 × 10 ⁶	7.0 × 10 ⁻⁴	0.47	1.5 × 10 ⁻⁴
II	224	126	2.2 × 10 ⁶	5.8 × 10 ⁻⁴	0.57	1.0 × 10 ⁻⁴
III	680	616	1.0 × 10 ⁷	6.2 × 10 ⁻⁴	0.91	6.8 × 10 ⁻⁵

Doubly labelled RSV was prepared as described in Fig. 1 and the nucleic acids were extracted as described in Bishop *et al.*³. Infectivity assays were performed as described in Levinson⁴, and are expressed as focus forming units (f.f.u.)/ml.

located on the surface of the virion, intact RSV labelled with ³H-thymidine was treated with deoxyribonuclease. The data in Table 3 demonstrate that the bulk of the DNA is located on the interior of the particle or is protected in some other manner from degradation by deoxyribonuclease.

In addition, we examined both the size of the DNA and its relationship to the RNA of the virion. In rate zonal centrifugation in a 15–30 per cent sucrose gradient, using ³²P-labelled SR-RSV RNA as a marker, the bulk of

min) preparations of ³H-thymidine labelled nucleic acid from RSV were analysed by acrylamide gel (2.25 per cent) electrophoresis according to the procedure of Bishop *et al.*³. As shown by Duesberg⁶ and by Montagnier *et al.*⁷, heating the RNA in this manner causes the 65S RNA to dissociate into 35S sub-units.

Fig. 3A demonstrates that, on electrophoresis, the unheated DNA migrates in two principal bands in the vicinity of the 65S RNA marker. The 4S viral RNA marker can also be seen. Analyses of the heated mixture (Fig. 3B) shows that the 65S RNA marker has dissociated and now migrates in a heterodisperse fashion at approximately 30–40S (refs. 6, 7) but the bulk of the DNA migrates similarly to the unheated DNA. Because there is no indication that a significant amount of ³H-thymidine migrates with the sub-units of RSV-RNA, it is unlikely that most of the DNA is covalently bonded to the 65S viral RNA.

We conclude that the DNA we have characterized is not an artefact of the adsorption of cellular DNA to the virion; it is probably located in the interior of the particle.

Fig. 3. Acrylamide gel electrophoretic analysis of unheated and heated ³H-thymidine-labelled nucleic acid from RSV. ³H-thymidine and ³²P-labelled nucleic acids from RSV were prepared as described in Fig. 2. A mixture of these nucleic acids was electrophoresed on 17 cm, 2.25 per cent acrylamide gels for 4–7 h at room temperature. A, Unheated; B, heated at 80° C for 1 min. —, ³H-thymidine; ---, ³²P.

the DNA sediments slightly ahead of the 4S component of the RSV-RNA (Fig. 2). A small amount of DNA co-sediments with the 65S genome RNA. It is of great interest that the two components of the DNA obtained from the virion sediment at approximately the same rate as the two DNA products synthesized *in vitro* by the recently identified virion RNA-dependent DNA polymerase (manuscript in preparation).

To determine whether some of the DNA was covalently bonded to the 65S RNA, unheated and heated (80° C, 1

The virion DNA may be the result of abortive synthesis during the maturation of the virus, but it could possibly represent either the template for a putative DNA-dependent DNA polymerase or cellular DNA incorporated into the virion during maturation.

This work was supported by grants from the US Public Health Service, the California Division of the American Cancer Society and by the University of California Cancer Coordinating Committee.

Formation of Viral RNA-DNA Hybrid Molecules by the DNA Polymerase of Sarcoma-Leukaemia Viruses

by

MAKOTO ROKUTANDA
HINAE ROKUTANDA

St Louis, Missouri 63104

Viral RNA is the template for the DNA polymerase of the sarcoma-leukaemia viruses: a "natural" RNA-DNA hybrid is formed by the viral DNA polymerase, and a "synthetic" RNA-DNA hybrid is formed by annealing viral RNA with the DNA product of the DNA polymerase reaction.

WE have postulated that RNA tumour viruses possess a DNA polymerase dependent on viral RNA (ref. 1) and several laboratories have recently reported that leukaemia and sarcoma viruses of the mouse, chicken and cat incorporate radioactive deoxyribonucleotides into an acid-insoluble form²⁻⁵. As well as showing that information can flow from RNA to DNA, this system may provide unique information for the understanding of carcinogenesis. Although it is clear that DNA is the reaction product, the evidence that viral RNA is the template has been indirect; pretreatment of virus particles with large amounts of ribonuclease inhibits subsequent enzyme activity; RNA tumour viruses contain a 70S RNA component but little DNA.

We describe here two lines of evidence demonstrating that viral RNA is the template for the murine sarcoma virus (MSV) DNA polymerase: first, viral RNA-DNA hybrid molecules are formed by the MSV DNA polymerase and second, the DNA product formed by the MSV DNA polymerase hybridizes with viral RNA.

Viral RNA-DNA Hybrids

We have characterized previously the DNA polymerase present in MSV (ref. 4). The standard assay is conducted in a final volume of 100 μ l. containing 40 mM Tris buffer (pH 8.1), 30 mM NaCl, 5 mM dithiothreitol, 2.5 mM $MgCl_2$, 0.01 per cent 'Nonidet P40', 0.1 mM dATP, dGTP, dCTP, and 10 μ Ci of 3H -TTP (11.4 Ci/mmol). Enzyme activity

is linear with time for at least 90 min and is proportional to virus concentration from at least 2 to 20 μ g of viral protein per 100 μ l. All four deoxyribonucleotides are incorporated into an acid-insoluble, alkali-stable, deoxy-ribonuclease-digestible product.

To determine whether a viral RNA-DNA hybrid is synthesized by the viral DNA polymerase, MSV(M) containing ^{32}P -labelled viral RNA was used in the standard enzyme assay with 3H -TTP as the labelled deoxyribonucleotide precursor of DNA. The reaction was stopped after 0, 15, 30, 60, and 90 min and the products were analysed by zone sedimentation (Fig. 1). In the conditions used, ^{32}P -labelled viral RNA sediments about two-thirds down the tube. No significant amount of 3H -labelled material from the zero time reaction sediments in this 70S region, but products of increasing times of reaction include increasing amounts of 3H -DNA co-sedimenting with 70S RNA. At 90 min, more than 8,000 c.p.m. of the 3H -DNA product from 50 μ l. of reaction mixture co-sediments with 70S RNA.

The peak fraction containing both 70S ^{32}P -RNA and 3H -DNA were pooled as a "hybrid fraction" for further study. The hybrid fraction was treated with pronase (125 μ g/ml. for 1 h at 37°C) and recentrifuged in a sucrose density gradient. Again the 3H -DNA and ^{32}P -RNA sedimented in the same 70S position, indicating that the DNA and RNA were not held together by a protein link. Stronger evidence for the hybrid nature of the product

Fig. 1. Zone sedimentation of the product of the MSV DNA polymerase reaction. The Moloney isolate of murine sarcoma virus, MSV(M), purified from the growth medium of the MSV(M) transformed rat cell line, 78A1⁴, was used in these experiments. ^{32}P -labelled MSV(M) was purified from the media of fifty 78A1 monolayer cultures (250 ml. Falcon plastic) grown for 24 h in Eagle's minimal essential medium (containing one-fourth the normal phosphate concentration) with 10 per cent foetal calf serum containing 50 μ Ci/ml. of carrier-free ^{32}P . Purified virus was dialysed for 3 h against 0.01 M Tris-HCl (pH 8.1). Five 200 μ l. amounts of virus (34.5 μ g of protein) were made up to 500 μ l. containing the standard assay mixture with 50 μ Ci of 3H -TTP. At 0, 15, 30, 60 and 90 min of incubation at 37°C, one assay tube was removed, and the reaction stopped by the addition of 10 mM EDTA and 0.5 per cent SDS. The preparations were layered over 11.4 ml. linear 15–30 per cent sucrose gradients in 0.01 M Tris-HCl (pH 7.4)—0.1 M NaCl—0.001 M EDTA, and centrifuged at 4°C for 3.5 h in the Spinco 'SW41' rotor at 36,000 r.p.m. Fractions (0.5 ml.) were collected and 50 μ l. aliquots plus 100 μ g of carrier calf thymus DNA were precipitated with 0.6 M trichloroacetic acid and collected on membrane filters. The acid-insoluble 3H and ^{32}P c.p.m. were determined in a Beckman liquid scintillation spectrometer. (^{32}P c.p.m. at the top of the gradient represent viral envelope phospholipid and 4–5S RNA present in tumour viruses. 3H c.p.m. at the top are mostly 3H -TTP from the assay mixture and also some free 3H -DNA product.) ○—○, Viral ^{32}P -RNA; ●—●, 3H -DNA product.

Fig. 2. Equilibrium sedimentation of the viral RNA-DNA hybrid fractions in Cs_2SO_4 density gradients. The peak fractions containing ^3H -DNA and/or viral ^{32}P -RNA after zone sedimentation of the 0 and 60 min reaction products (Fig. 1) were pooled and dialysed against $0.1 \times \text{SSC}$ ($\text{SSC} = 0.15 \text{ M NaCl}-0.015 \text{ M sodium citrate}$). Two hundred μl . of hybrid and 20 μg each of mouse cell DNA and RNA (absorbance markers) were made up to a final volume of 3.1 ml. in $2 \times \text{SSC}$, 2.60 g of Cs_2SO_4 (Harshaw Chemical Co.) were added, and the tubes were centrifuged at 20°C for 84 h in the Spinco 'SW39' rotor at 33,000 r.p.m. Fractions (0.17 ml.) were collected and the refractive index, absorbance at 260 nm, and acid-precipitable radioactivity determined.

was obtained using equilibrium band sedimentation in a Cs_2SO_4 gradient which resolves DNA from RNA by density. As shown in Fig. 2a, the 70S ^{32}P -RNA band is at a density close to that of the cell RNA marker ($\rho \approx 1.68 \text{ g cm}^{-3}$) and distinct from that of the cell DNA marker ($\rho \approx 1.44 \text{ g cm}^{-3}$). But the 60 min ^3H -DNA band is coincident with viral ^{32}P -RNA (Fig. 2b). Treatment of the hybrid fraction with 0.2 M NaOH for 20 min at 80°C before density gradient analysis—which would hydrolyse RNA—lowers the density of the ^3H -DNA component to that of free DNA (Fig. 2c). Three additional hybrid fractions were analysed with similar results. We conclude: (1) that the immediate product of the MSV DNA polymerase reaction is a viral RNA-DNA hybrid; and (2) that only a small portion of each RNA molecule seems to participate in hybrid duplexes, for the buoyant density of the hybrid is close to that of viral RNA.

The RNA- ^3H -DNA fractions isolated by zone sedimentation of reaction mixtures after 30, 60 and 90 min were sedimented through alkaline sucrose gradients which free polynucleotide chains from one another. After 10 h at 36,000 r.p.m. in the 'SW41' rotor (Fig. 3), ^{14}C -DNA released from marker adenovirus sediments at 34S near the bottom of the tube. The alkali-released ^3H -DNA from the hybrid sediments close to 7S in six determinations. This corresponds to a molecular weight of single-stranded DNA of about 200,000 daltons (Table 1).

Table 1. SIZE OF DNA IN VIRAL RNA-DNA HYBRID

Incubation (min)	Sedimentation coefficient in alkali*	Mol. wt.†
30	6.3	155,000
30	5.9	150,000
60	6.7	181,000
60	6.7	181,000
90	7.7	255,000
90	6.8	188,000

* Sedimentation coefficient in alkali determined in Fig. 3.

† Molecular weight of single stranded DNA calculated from S value as described by Studier⁴.

Further evidence that viral RNA is the template for the MSV DNA polymerase was obtained by annealing viral 70S ^{32}P -RNA with enzymatically synthesized ^3H -DNA and analysing the product by equilibrium sedimentation in Cs_2SO_4 density gradients. When viral RNA and DNA are mixed but not annealed, the viral DNA band is at the density of unhybridized DNA (Fig. 4a). But the incubation of viral ^{32}P -RNA with ^3H -DNA in annealing conditions converts viral DNA to a hybrid—it again coincides with viral RNA (Fig. 4b).

Does the Virus contain DNA?

RNA tumour viruses are assumed to contain only RNA but because DNA might serve as a template for the viral DNA polymerase, we attempted to determine whether MSV(M) contains appreciable amounts of DNA. We isolated MSV(M) from the media of 78A1 cells grown for 24 h in the presence of 2 mCi of ^3H -thymidine; the purified preparation represented 2.21 mg of protein and 41,840 c.p.m. (^3H). Thus less than 120,000 daltons of DNA are present per virus particle (on the basis of the specific radioactivity of newly synthesized cell DNA and an assumed virus particle content of 60 per cent protein and 2 per cent RNA and a particle weight of 450×10^6 daltons^{7,8}).

MSV (^3H -thymidine pre-labelled) was used in the standard enzyme assay with ^{32}P -TTP as the labelled deoxyribonucleotide precursor of DNA. The reaction mixture was treated with 0.5 per cent sodium dodecyl sulphate and analysed by zone sedimentation. Most of the

Fig. 3. Zone sedimentation of ^3H -DNA from RNA- ^3H -DNA hybrids in alkaline sucrose density gradients. The 30 min (200 μl), 60 min (150 μl), and 90 min (100 μl) hybrid fraction, isolated as described in Fig. 1, plus 3 μl . of ^{14}C -thymidine labelled adenovirus type 7 were layered on 11.3 ml. linear 5–20 per cent sucrose gradients in 0.3 M NaOH–0.7 M NaCl–0.001 M EDTA, and centrifuged at 4°C for 10 h in the Spinco 'SW41' rotor at 36,000 r.p.m. Fractions (0.75 ml.) were collected and the acid-insoluble, alkali-stable radioactivity was determined⁴. \circ — \circ , Adenovirus DNA marker; \bullet — \bullet , DNA product from RNA-DNA hybrid.

^{32}P -DNA product sedimented to the position of the RNA-DNA hybrid but ^3H c.p.m. from pre-labelled virus did not co-sediment with the DNA product. Thus the ^3H -thymidine-labelled material in MSV does not seem to participate in the formation of the ^3H -DNA-containing hybrid. The small amount of ^3H -thymidine present in the virus preparation may represent DNA in structures contaminating the virus preparation, or possibly the natural DNA product of the viral DNA polymerase.

Significance of the DNA Product

Our experiments strongly argue that viral RNA is the template for the DNA polymerase present in the murine sarcoma virus for (1) a "natural" viral RNA-DNA hybrid is formed during the enzymatic reaction, and (2) a "synthetic" RNA-DNA hybrid is formed by annealing the DNA product with viral RNA. The viral RNA-DNA hybrid is probably the initial product of the MSV DNA polymerase reaction for only small amounts of free DNA product are found even after 90 min of reaction.

produce hybrid structures longer than about 2-7 per cent of the viral genome would then have to be explained. Nuclease activities might degrade the rest of the chain formed *in vitro*, or perhaps host cell or viral induced gene products are required to transcribe the entire viral genome into DNA. The second alternative opens up several possibilities: this piece(s) of DNA may, for example, code for critical protein(s) in viral development. The distinction between these two possibilities is especially important, for the role of viral DNA appears, on the basis of inhibitor studies, to be essential for both viral replication and cell transformation¹. The mechanism of carcinogenesis by sarcoma-leukaemia viruses may even provide a model for possible reversal of RNA transcription during normal cell function, such as the intriguing expression of RNA tumour virus genetic information by cellular genes during embryonic development in the mouse¹⁰.

We thank Miss Mary Beranek, Miss Maria Cartas, and Mrs Clara Boudreau for assistance and Dr David

Fig. 4. Hybridization of viral ^{32}P -RNA with the ^3H -DNA product of the MSV DNA polymerase. Viral ^{32}P -RNA was prepared from ^{32}P -labelled MSV(M) and ^3H -DNA was prepared from a 60 min reaction mixture as follows: after the addition of 0.5 per cent sodium dodecyl sulphate, the preparations were extracted three times with phenol saturated with 0.1 M NaCl-0.01 M Tris-HCl (pH 7.4)-0.001 M EDTA. The aqueous layer was dialysed against $0.1 \times \text{SSC}$. The ^3H -DNA preparation was treated with 0.2 N NaOH at 80°C for 20 min and neutralized to denature the DNA and destroy unlabelled viral RNA. Denatured ^3H -DNA (4,400 c.p.m.) and $5.8 \mu\text{g}$ of viral ^{32}P -RNA (40,500 c.p.m./ μg) in $400 \mu\text{l}$ of $2 \times \text{SSC}$ were annealed at 60°C for 9 h. An identical mixture of ^3H -DNA and ^{32}P -RNA, not annealed, served as a control. Both samples were centrifuged to equilibrium in Cs_2SO_4 gradients and processed as described in Fig. 2.

The DNA component in an individual hybrid duplex moves at 7S, corresponding to a molecular weight of 200,000. A similar value is obtained for the average amount of DNA formed per virus particle in a 90 min enzyme reaction (see Fig. 1, calculated from $3.45 \mu\text{g}$ of viral protein per $50 \mu\text{l}$ reaction mixture, 8,000 c.p.m. incorporated into DNA, assuming equimolar amounts of A, G, C and T in the DNA product and a 60 per cent protein content and 450×10^6 particle weight for the virus^{7,8}). These findings confirm the correspondence between the RNA-DNA hybrid and the free 70S viral RNA: apparently only a small fraction of each RNA molecule is in hybrid form.

Further experiments must resolve whether (1) the complete viral genome is transcribed to DNA *in vivo* or (2) the production of a specific short piece(s) of DNA is a true function of the polymerase. According to the first alternative, the hybrid may be an intermediate in the replication of virus or in the production of transforming DNA, but the failure of the *in vitro* enzyme reaction to

Besides having RNA-dependent DNA polymerase activity, oncogenic RNA viruses possess a DNA-directed DNA polymerase which is distinguished from previously described enzymes of this type in preferring double-stranded DNA as template and yielding a principally double-stranded product.

Temin¹ and Baltimore² recently reported the existence of an RNA-directed DNA polymerase in oncogenic RNA viruses. We confirmed these findings with six oncogenic viruses and further established³ the following features of the reaction: (a) physical and chemical characterizations proved that the product was in fact a DNA heteropolymer; (b) molecular hybridization showed that the DNA synthesized was complementary to the viral RNA contained in the enzyme preparation; and (c) RNA-DNA complexes were detected as early components in the polymerization. The specific complementarity of the synthetic DNA to viral RNA and the early appearance of RNA-DNA hybrids implied that the viral RNA functioned as a template in the synthesis of the DNA.

The heritably stable state that characterizes cells transformed by these oncogenic agents seems to require integration of the newly synthesized DNA into the genome of the cell. It is unlikely that the RNA-DNA hybrids detected as presumptive intermediates in the reaction can serve this purpose. It is more likely that the single-stranded DNA has to be converted into its double-stranded equivalent for integration, a conversion that would necessitate a DNA-directed DNA polymerase. We therefore pointed³ to the need to search for such an enzyme, either in the virion or in the infected cell, which would presumably be characterized by its ability to use duplexes to generate duplexes. We have now examined six oncogenic RNA viruses—Rauscher leukaemia virus (RLV), Rous sarcoma virus RSV-(RAV-1), avian myeloblastosis virus (AMV), murine mammary tumour virus (MTV), Moloney sarcoma virus (MSV) and the feline leukaemia virus (FeLV)—and encountered a DNA-directed DNA polymerase in the virions of all of them. We report here some of the properties of the reactions and the products formed.

Previously³, we alluded to two observations in prolonged syntheses that could not be explained solely by the RNA-directed DNA polymerase activity we were studying. The base composition of the product of an extensive synthesis seemed to be more identical than complementary to the viral RNA. This implied that the DNA complement made early in the reaction was subsequently used as a template for the formation of a complement to itself. In addition, although early products are all hybridizable, late DNA components appear that do not complex to viral RNA (unpublished observations). The implication is that these late DNA products are either duplexes or single strands identical in sequence to the viral RNA. All this suggests the presence of a DNA-directed DNA synthesis in which the DNA formed initially serves as a template for subsequent polymerization.

Evidence for a DNA-directed DNA Polymerase

In the experiment documented in Table 1, the addition of either *Escherichia coli* DNA or mouse embryo fibroblast

(MEF) DNA results in a striking stimulation of ³H-dATP incorporation. A trivial explanation of this would invoke protection by the added DNA against nucleolytic degradation of the DNA synthesized by the RNA-directed polymerase. To test—and eliminate—this, and at the same time provide a more convenient system for studying the DNA-directed step, it was necessary to eliminate the RNA-directed activity. This can be done by destroying the resident viral RNA by previous treatment of the disrupted virions with a suitable nuclease. Micrococcal nuclease is convenient because it requires Ca²⁺. Its activity can consequently be readily neutralized by the specific chelating agent ethyleneglycol-bis-(aminoethyl ether)tetraacetic acid (EGTA). Fig. 1 shows the kinetics of DNA synthesis in four oncogenic viral preparations that had been pretreated with micrococcal enzyme. There is little residual activity in the absence of added exogenous nucleic acid; the addition of DNA leads to an excellent response in all four enzyme preparations.

Table 2 shows that the DNA-stimulated reaction requires all four deoxyriboside triphosphates as well as Mg²⁺. The last control recorded in Table 2, omission of the viral enzyme, was included to eliminate the unlikely possibility that the enzyme we were detecting was present as a contaminant of the micrococcal nuclease used to eradicate the RNA-directed step.

Table 1. STIMULATION OF THE AMV POLYMERASE BY DNA

DNA	-DNA	+DNA
	c.p.m.	
<i>E. coli</i> (4.0 µg)	631	3,460
MEF (1.5 µg)	840	4,340

A standard incubation mixture of 1 ml. contains in µmoles: 50 Tris-HCl (pH 8.3), 12 MgCl₂, 40 KCl, 2 dithiothreitol, 0.8 each of the non-labelled deoxyribonucleoside triphosphates and 0.04 labelled deoxyribonucleotide. In this experiment, ³H-dATP was used at a specific activity of 330 c.p.m. The incorporations represent those observed in 0.1 ml. aliquots, corresponding to 15 µg viral protein. Virus particles suspended in 0.01 M Tris (pH 8.3) at 300 µg viral protein/ml. were preincubated 10 min at 0° C in the presence of 0.2 per cent 'Nonidet P-40' detergent with dithiothreitol at 30 mM. The virus was then added to a standard incubation mixture at a level of 130 µg/ml. and incubated at 37° C for 30 min. The reaction was terminated by the addition of 0.5 ml. water and 0.3 ml. trichloroacetic acid (TCA) mixture (equal volume mixture of 100 per cent TCA solution, saturated sodium orthophosphate, and saturated sodium pyrophosphate). After 10 min, the precipitable radioactivity was collected on a nitrocellulose filter, dried, and the radioactivity determined in a liquid scintillation counter using BBOT-toluene scintillation fluid. Mouse embryo fibroblast DNA and *E. coli* DNA were extracted following the procedure of Gillespie and S.S. and added to the reaction mixtures as indicated.

Table 2. REQUIREMENTS OF DNA-DIRECTED DNA POLYMERASE

Conditions	³ H-dAMP incorporated (c.p.m.)
Complete (12 mM Mg ²⁺ , 40 mM K ⁺)	
1 µg MEF DNA	404
-dCTP	55
-dGTP	15
-dATP	41
-Mg ²⁺	62
-Viral polymerase	30

Enzyme reactions were carried out as described in Table 1. The virus suspension was treated with micrococcal nuclease before incubation at 37° C, as described in Fig. 1. The specific activity of the ³H-dATP was 330 c.p.m./pmole.

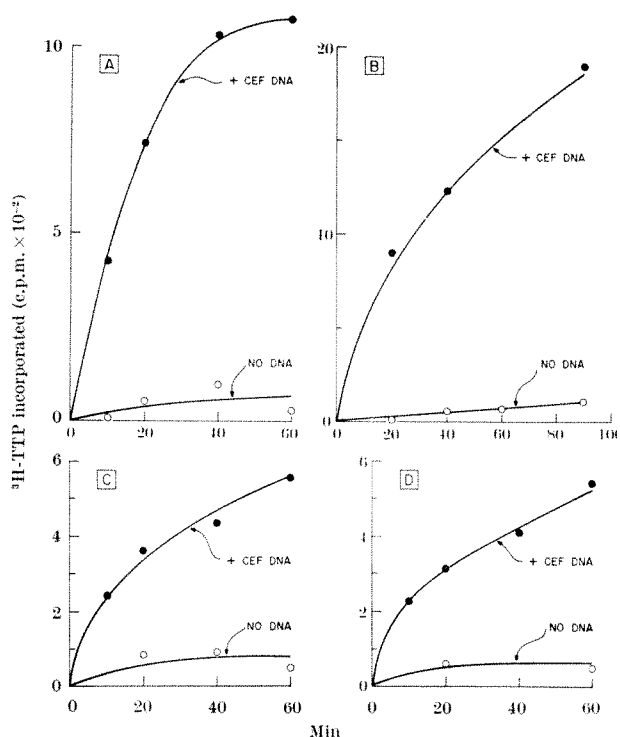

Fig. 1. Kinetics of incorporation of ^3H -TTP by DNA-directed DNA polymerases from (A) RSV-(RAV-1), (B) AMV, (C) RLV and (D) MTM. For each reaction, a 0.25 ml. of a standard reaction mixture (Table 1) was used. The specific radioactivity of ^3H -TTP was 1.4×10^5 c.p.m./pmole. Chick embryo fibroblast DNA at a concentration of $3 \mu\text{g}/0.25$ ml. reaction was used as template for the four DNA-DNA polymerases. The DNA was prepared as described previously⁷ from trypsinized chick embryos. The preparation, source, and purification of the viruses used have been described previously. To eliminate the RNA-directed reaction, all the virus preparations used were submitted to a non-ionic detergent treatment ('NP-40', Shell Co.) for 10 min at 0°C in the presence of 0.1 M dithiothreitol in volumes of about $25 \mu\text{l}$. The 'NP-40' concentrations were 0.2 per cent for RSV-(RAV-1) and AMV, 0.1 per cent for RLV, and 0.17 per cent for MTM. These were then diluted to $250 \mu\text{l}$ for digestion with nuclease from *Staphylococcus aureus* (Worthington); incubation was at room temperature for 30 min in the presence of $240 \mu\text{g}$ nuclease/ml. and 0.002 M Ca^{2+} . The nuclease action was stopped by adding EGTA to a final concentration of 0.004 M. Nucleoside triphosphates were then added and incorporation kinetics followed at 37°C . The amounts of viral protein per $30 \mu\text{l}$: A, $3.75 \mu\text{g}$; B, $3.90 \mu\text{g}$; C, $2.56 \mu\text{g}$ and D, $2.80 \mu\text{g}$. At the indicated times, $30 \mu\text{l}$ aliquots were withdrawn, precipitated with TCA in the presence of $60 \mu\text{g}$ of *E. coli* RNA as carrier, processed and counted as described in Table 1.

Nature of the Product

The product of an extensive synthesis was purified by phenol extraction and alcohol precipitation. It was then subjected to physical and enzymological tests. Table 3 shows that the acid-precipitable product can be degraded by deoxyribonuclease and spleen phosphodiesterase but not by ribonuclease or alkali. To confirm that it is DNA, the density of the product was examined by equilibrium density centrifugation in Cs_2SO_4 and the result is shown in Fig. 2. *E. coli* DNA was included as a density marker (1.426 g cm^{-3}). The density of the DNA synthesized in response to the addition of MEF DNA is found at the same density (1.420) as MEF DNA. The DNA produced by the RNA-directed reaction has³ the indicated density of 1.450.

The average size of the product is compared (Fig. 3) with that of template in neutral and alkaline sucrose gradients. It is clear that the radioactive product is smaller than the DNA used to stimulate the reaction; there is no evidence of covalent attachment of the product to the template.

Response to Various DNA Templates

Table 4 compares the response of the AMV DNA-DNA polymerase to different DNA templates. Unlike the thoroughly studied DNA-dependent DNA polymerase

Table 3. PROPERTIES OF DNA-DIRECTED PRODUCT OF THE AMV POLYMERASE

Treatment	TCA precipitable c.p.m.	Per cent
None	810	100
Ribonuclease (50 $\mu\text{g}/\text{ml}$.)	785	97
KOH (0.33 M, 18 h)	773	95
Deoxyribonuclease (120 $\mu\text{g}/\text{ml}$.)	177	22
Spleen phosphodiesterase (0.28 units/ml.)	14	1.7

The product DNA made on double-stranded MEF DNA template was synthesized using the standard incubation mixture on a 1 ml. scale. The specific activity of the ^3H -ATP used was 4,000 c.p.m./pmole. After reaction at 37°C for 2 h, the product was isolated by making the reaction mixture 0.4 M with respect to NaCl and 1 per cent sodium dodecyl sulphate (SDS) and extracting for 5 min at room temperature with an equal volume of a mixture of phenol-cresol (10:1). The aqueous phase was filtered through a 'Sephadex G-50' column (0.9×100 cm) and the purified material precipitated with alcohol. It was then dissolved in 0.01 M Tris- 0.1 M NaCl (pH 8.3) (TN buffer) and portions of this solution were used for the different experiments. The digestion with ribonuclease was carried out in 0.5 ml. TN buffer for 90 min at 37°C . Digestion with deoxyribonuclease was for 3 h at 37°C in TN buffer plus 0.005 M MgCl_2 . The reaction with spleen phosphodiesterase was in 0.02 M ammonium acetate buffer (pH 6.0) at 37°C for 2.5 h in 0.1 ml. The alkali treatment was in $20 \mu\text{l}$ in 0.33 M KOH for 18 h at 37°C .

of Kornberg⁴, these oncogenic viral DNA polymerases prefer double to single-stranded DNA. A particularly interesting example is the f1 DNA, a single strand DNA quite similar to that found in the DNA bacteriophage ϕX174 which has been shown⁵ to be an excellent template for the Kornberg enzyme. We have seen no signs of template function even in extensive incubations with f1 DNA. The f1-RF DNA, a covalently linked double-stranded circular DNA, is also inactive. This is not surprising because at least one of the two strands would have to be nicked before replication could commence.

Table 4. RESPONSE OF AMV DNA-DNA POLYMERASE TO VARIOUS DNA TEMPLATES

DNA	c.p.m. ^3H -TTP incorporated	Double-stranded	Single-stranded or denatured
<i>E. coli</i>	—	1,006	239
MEF	135	638	135
CEF	76	889	403
T6	120	2,320	460
f1	50	—	19
f1-RF	50	128	—

The reactions were in the standard conditions and processed as in Table 1. The ^3H -dATP had a specific activity of 350 c.p.m./pmole. Incubations were for 30 min at 37°C . DNA concentrations were about $3 \mu\text{g}/0.25$ ml.

Proof by Hybridization

The response to quite disparate DNA templates provides an excellent opportunity of deciding by molecular hybridization whether the DNA added is in fact serving as an instructive agent in the polymerization. The required DNA-DNA hybridization can readily be performed using the Denhardt⁶ modification of the Gillespie and Spiegelman⁷ method for hybridizing RNA to DNA fixed to membrane filters. We have found (Horowitz and S.S., unpublished observations) that including the

Fig. 2. Caesium sulphate equilibrium density gradient centrifugation of AMV DNA-DNA polymerase product. A 1 ml. standard reaction (Table 1) containing $133 \mu\text{g}$ viral protein, $9 \mu\text{g}$ MEF DNA, and ^3H -dATP at 4.1×10^5 c.p.m./pmole was incubated for 2 h at 37°C . The reaction mixture was deproteinized by phenol extraction at room temperature in the presence of 0.4 M NaCl and SDS 1 per cent final concentration. An aliquot of the purified product was mixed with saturated Cs_2SO_4 to a density of 1.550 and centrifuged at $33,000$ r.p.m. at 20°C for 60 h in a Spinco 'SW-56' rotor. *E. coli* DNA ($\rho = 1.426$) and ^{32}P -labelled 18S ribosomal RNA ($\rho = 1.660$) were used as internal markers. After centrifugation, fractions were collected from the bottom of the tube and processed as in Table 1.

alkaline wash used in the procedure of Warnaar and Cohen⁸ yields acceptable backgrounds.

Table 5 shows the results of hybridizing each of three DNA products to the three DNA templates used in the synthetic reactions. The data are clear cut: the hybridizability of each product is much superior when challenged with the DNA actually used in its synthesis. The percentages of the input counts hybridized in the homologous hybridizations of Table 5 are quite considerable: 10, 16 and 59 per cent for the mouse, *E. coli* and T6, respectively. For the mouse the value is surprisingly high in view of the complexity of the genome. We have obtained similar results with chicken DNA. Such data suggest that the DNA polymerase of the oncogenic viruses is not copying random segments of these vertebrate DNAs. Clearly it would be desirable to identify the components of the genome that are being chosen selectively for amplification.

Another feature of the hybridization experiments is exhibited in Table 6 which examines the effect of denaturation on the ability of the synthesized DBA to hybridize to its homologous templates. Denaturation strikingly augments the amount of product available for hybrid formation. The results suggest therefore that much (70–80 per cent) of the DNA synthesized is in the double-stranded state.

Conclusions

While eliminating the resident RNA template an opportunity is presented to examine the acceptability of other RNA molecules by the RNA-directed polymerase. Experiments along these lines will be reported later.

The fact that the DNA-directed polymerases described here readily accept—indeed prefer—double-stranded DNA as templates distinguishes them from the DNA-dependent DNA polymerases so far reported. If the oncogenic viral polymerases are in fact true replicases, they should

Table 5. HYBRIDIZATION OF DNA-DIRECTED PRODUCTS TO VARIOUS DNAs

DNA on filter	Mouse	<i>E. coli</i>	T6
Mouse	8,698 (100%)	587 (6%)	1,477 (2%)
<i>E. coli</i>	454 (5%)	7,724 (100%)	197 (0.4%)
T6	152 (2%)	168 (2%)	54,673 (100%)

Radioactive material in each hybridization was equivalent to 3.3×10^4 , 4.9×10^4 and 9.4×10^4 c.p.m. for DNAs synthesized with mouse, *E. coli*, and T6 DNA, respectively. The numbers represent c.p.m. found per 150 μ g of DNA on the filter; those in parentheses represent percentage of that observed in the homologous hybridization. Products were prepared as described in Table 3, and dissolved in 0.5 ml. of 0.07 \times SSC (1 \times SSC = 0.15 M NaCl–0.015 M sodium citrate, pH 7). The hybridization reactions were carried out using DNA immobilized on membrane filters and product DNA in solution in 200 μ l. of 3 \times SSC at 66° C for 12 h. For denaturation, 100 μ l. of the product was made 0.1 M with respect to KOH and kept at room temperature for 10 min. The solution was then neutralized with an equivalent amount of HCl and diluted to a final volume of 200 μ l. with a calculated amount of SSC solution so that the final solution was 3 \times SSC. The filters were loaded with 100–150 μ g of denatured DNA, allowed to dry at room temperature, and then transferred to a vacuum oven at 80° C for 2 h at a pressure of 25 mm Hg. The filters were pre-incubated in Denhardt's solution (0.02 per cent bovine serum albumin, 0.02 per cent Ficoll and 0.02 per cent polyvinylpyrrolidone in 3 \times SSC) at 66° C for 6 h immediately preceding hybridization. After hybridization for 12 h, the filters were taken out; each was washed on either side with 100 ml. of 10^{-3} Tris (pH 9.3), dried and counted. c.p.m. fixed in homologous hybridizations are italicized.

Table 6. HYBRIDIZATIONS OF NATIVE AND DENATURED PRODUCT DNA WITH TEMPLATE DNA

DNA	Native	Denatured
Mouse	2,878	8,698
<i>E. coli</i>	2,098	7,724
T6	10,834	54,673

The same products and conditions are used here as for the experiment of Table 5. The "native" was not, however, subjected to the alkaline treatment as in the legend of Table 5.

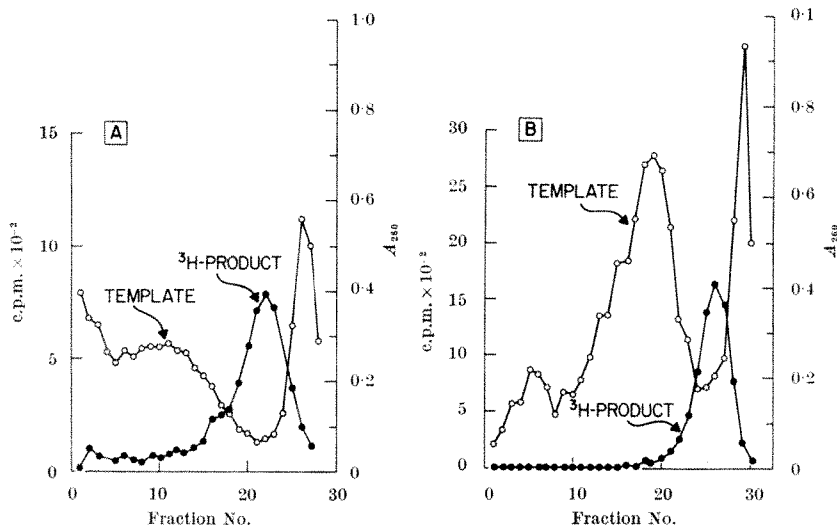

Fig. 3. Neutral and alkaline sucrose gradient centrifugation of AMV DNA-DNA polymerase product. A 1 ml. reaction containing 133 μ g of AMV protein pretreated as described in Fig. 1, 9 μ g of *E. coli* DNA, and ^3H -dATP (4×10^5 c.p.m./pmole) was incubated for 2 h at 37° C and the product purified as described in Fig. 2. 180 μ g of the *E. coli* DNA used as template and an aliquot of the product of the reaction were layered on (A) neutral (8–22 per cent sucrose–0.01 M Tris (pH 8.3)–0.25 M NaCl) or (B) alkaline (8–22 per cent sucrose–0.25 M NaOH (pH 12.4)–0.05 M EDTA) sucrose gradients. Each gradient was prepared on a 0.5 ml. cushion of 70 per cent sucrose. Centrifugation was at 40,000 r.p.m. and 4° C for 5.5 h in the Spinco 'SW-41' rotor. Fractions were collected from the bottom of the tube and processed as in Table 1.

initiate chains, a feature that can be examined in syntheses with γ - ^{32}P -labelled deoxyribonucleotides.

All the six oncogenic RNA viruses which we have examined possess the DNA-directed polymerase, but this activity could not be detected in five non-oncogenic viruses: reo, polio, influenza, vesicular stomatitis and Newcastle disease viruses.

It is now clear that RNA oncogenic viruses contain two DNA polymerase activities: one which uses single-stranded RNA as a template and in the process generates a DNA–RNA hybrid; and a second, described here, which accepts double-stranded DNA as a template and yields a principally double-stranded product. The primary function of the latter may be to amplify the oncogenic DNA duplex once it is formed. The multiple copies so produced could markedly increase the probability of a successful integration. It is, of course, still necessary to clarify how the DNA–RNA hybrid is converted to the DNA–DNA duplex, a necessary reaction which we believe is occurring in our preparations. Is a third catalytic function required or can one of the two activities we have already identified mediate this step? The use of suitably constructed DNA–RNA structures should resolve this problem. It will be necessary to purify the relevant proteins and tackle the formidable problem of the logistics of preparing purified viruses in amounts adequate for a realistic attempt at this kind of enzymology.

We thank Drs Peter Modell and Norton Zinder for the f1 bacteriophage and the RF DNA. Drs John Moloney, Frank Rauscher, and Tim O'Connor of the Special Virus Cancer Programme (SVCP) of the National Cancer Institute for help, and the personnel of the laboratories associated with the SVCP for their cooperation. The work was supported by a contract with the SVCP of the US National Cancer Institute and a NCI grant.

A reconstruction of the asymmetric unit of the chromatoid body helix from electron microscopic data corresponds to a particle which in many ways resembles the ribosome.

THE chromatoid bodies found in cysts of *Entamoeba invadens* are composed of ribonucleoprotein particles arranged in closely packed helices. Because of the size of the units (about 200 Å), it has been thought that the units are related to ribosomal particles, and this assumption is supported by the following evidence: most of the absorption at 260 nm occurs in the chromatoid body of the cell cross-section¹; no individual ribosome-like particles are observed in electron micrographs of sections except in close proximity to chromatoid bodies; cytochemical tests indicate that the chromatoid body contains ribonucleoprotein²; and calculation shows that the number of ribosomes expected in a cell is about equal to the number of units found in the chromatoid bodies of an average cyst³. These regular arrays of ribosome-like particles constitute a unique material for the analysis of ribonucleoprotein structure by electron microscopy, optical diffraction, and numerical image processing.

A model has been proposed⁴ for the packing of units in the chromatoid body on the basis of an optical diffraction analysis of an electron micrograph. This study concluded that the helical symmetry was described by the selection rule $l = 5n + 12m$, that is, twelve units in one helix repeat five turns long. A second study by Morgan⁵ attempted to apply a method suggested by DeRosier and Klug⁶ for the reconstruction of a three dimensional object from electron microscopic data. DeRosier and Klug⁷ raised three objections to Morgan's article and believed that analysis to be incorrect. Here, after presenting a case for choosing a somewhat different symmetry for the helix, we describe an optical and computational reconstruction of the unit of the chromatoid body helix.

Three Dimensional Reconstruction

DeRosier and Klug⁶ demonstrated the feasibility of doing three dimensional structural studies from electron micrographs in their study of the tail of bacteriophage T4. Their procedure is based on what is known to crystallographers as the projection theorem, which states that the Fourier transform of a three dimensional structure projected onto a plane is a section through the Fourier transform of the three dimensional structure. By tilting a specimen in the electron microscope one could collect sufficient data to fill Fourier space adequately. The Fourier coefficients, thus collected, could then be inversely Fourier transformed to reconstruct the specimen in three dimensions. Alternatively, they pointed out that if rotational or screw symmetry exists it may be used to lessen the number of views required to perform a three dimensional reconstruction. In carrying out a reconstruction from an electron micrograph one must consider the relationship between the distribution of absorbance on the micrograph and the distribution of stain in the specimen. To relate the distribution of stain in the object to the distribution of absorbance in the recorded image, the

amplitude contrast⁸ formalism was used. (Those micrographs which were numerically processed by computer in this analysis were all taken sufficiently close to focus so that the first interference maxima⁹ as assessed by optical diffraction patterns appeared at reciprocal spacings greater than $1/12 \text{ Å}^{-1}$. This minimized phase contrast¹⁰ at the level of resolution where we worked and thereby justified the use of the amplitude contrast formalism.)

Structural Analysis

The interpretation of micrographs of positively stained and sectioned crystalline or semi-crystalline material must circumvent a number of difficulties which are not ordinarily encountered in studies of isolated negatively contrasted particles. These involve the orientation of sections and their thickness; but sectioned materials offer the advantage of preserving dimensions¹¹ better than negatively contrasted material. Both the orientation of a

Fig. 1. Electron micrograph of a positively contrasted chromatoid body sectioned along the helical axis. "One sided" helices with intact peripheral regions are shown in region A and "two sided", truncated helices are shown in region B.

Fig. 2. *a*, The optical diffraction pattern obtained from a highly defocused image of a section of a chromatoid body (the first interference maxima is at a reciprocal spacing of about $1/70 \text{ \AA}^{-1}$), demonstrating the selective heightening of certain spatial frequencies in a defocused image. *b*, An optical diffraction pattern from a one-sided helix. The helical symmetry is described by the selection rule $l = 5n + 17m$. There are no restrictions on n . *c*, The "one-sided" diffraction pattern shown in *b* has been optically filtered to show more clearly the back half of the helix by removing noise and information arising from the front side. Most interesting are the grooves near the top of the image (region *A*) which are perpendicular to the (3, 2) direction and which give rise to the (3, 2) diffraction term. These grooves disappear near the lower part of the image (region *B*) where the outer part of the helix has been removed by sectioning. This is in agreement with predictions from the three dimensional structure. Stain is represented by light.

section and its thickness may substantially affect the electron microscope image and its optical diffraction pattern. It was found that by interpreting images of sections of the chromatoid body less than one helix diameter thick (600 Å) one could determine both orientation and section thickness quite accurately (unpublished).

A thickness of about 400 Å (as shown in Fig. 1) was found to be optimum when all factors were considered. Thicker sections provided less contrast, presumably because more lead grains overlap in the projected image. Sections less than 600 Å thick allowed an easy determination of thickness, and prevented images from being degraded by overlapping helices. With thicker sections individual helices necessarily overlapped. An analysis of the optical diffraction patterns of sections indicated that the chromatoid body was not crystalline. As a result of this lack of crystalline order (Fig. 2*a*) between helices, these overlapped images were of little value for structural analysis. In practice, the helical axes were not perfectly straight nor the sections perfectly planar so that when sections were too thick, other helices entered and left the section, causing overlapped images. These factors were balanced against the realization that using the projected image of less than one entire helix introduced errors into the three dimensional stain map. It was necessary to screen a vast number of sections of chromatoid bodies in order to select those few which were oriented very closely parallel to the helical axes and at the same time were of the appropriate thickness and quality. More than a hundred of these images were photographed and analysed by optical diffraction: those we have chosen for three dimensional

reconstruction are, in our opinion, the best thickness, compromise which is now feasible.

Individual helices were masked from images of the chromatoid body sectioned parallel to the helical axis (Fig. 1). Optical diffraction patterns (Fig. 2*b*) of these individual helices indicated that the helices could be described by the selection rules $l = 5n + 12m$, $l = 5n + 17m$, or $l = 7n + 19m$. The positions of the maxima measured from the ten most intense layer lines, indicated that the "average" radii calculated for these selection rules were 205 Å, 250 Å and 280 Å respectively. The maximum diameter of a helix was measured from the image to be $600 \text{ Å} \pm 20 \text{ Å}$. A uniform density 600 Å diameter helix has an average radius of 200 Å. This seemed to suggest a selection rule of $l = 5n + 12m$ in accordance with the analysis of an optical diffraction pattern of an entire section⁴. The Fourier transforms calculated by computer from individual helices, however, provided not only diffraction intensities but phases as well. On each layer line in the region in which contributions from only one Bessel function are present* the complex Fourier transform is either symmetrical about the meridian (when the order of the Bessel function is even) or is antisymmetrical about

* In the region of a helical transform in which there is no overlap of various orders of Bessel functions the three dimensional Fourier transform on any layer plane, L , is given by¹² $F_L(R, \psi) = G_n(R) e^{i n (\psi + \pi/2)}$ where R and ψ are the polar coordinates of a point in reciprocal space and n is the order of the Bessel function contributing to that layer plane. If the helical axis is aligned perpendicular to the optical axis of the electron microscope, the amplitudes on the right and left hand sides of the L th layer line of the transform of the electron microscope image are symmetric about the meridian while the phases differ by a factor of $e^{-i n \pi}$. That is, if n is even, the right and left hand sides of the complex transform are equal and if n is odd, the right and left hand sides are of opposite sign.

Fig. 3. Computer generated amplitude and phase along the second layer line obtained from three different "two sided" helices. In the region from $1/500 \text{ \AA}^{-1}$ to $1/170 \text{ \AA}^{-1}$, the phases on either side of the meridian differ by π in accordance with only the third order Bessel function contributing to the transform. There is no symmetrical behaviour which the phases or the amplitudes must have at reciprocal distances greater than $1/140 \text{ \AA}^{-1}$, and there is no simple relationship between the phases and amplitudes of different helices at these spacings.

the meridian (when the contributing Bessel function is of odd order). Thus from the intense fifth layer line we determined that the selection rule $l = 7n + 19m$ was invalid. The phases on the second layer line calculated from three "two sided" helices indicated that the contributing Bessel function must be of odd order (see Fig. 3)*. This, in our opinion, indicates that the helix can only be described by the selection rule $l = 5n + 17m$. Other layer lines (most notably $l = 3$ and $l = 7$) of the transforms of two sided images confirm this indexing. The helical symmetry is sufficiently high to allow us to reconstruct the asymmetric unit at a resolution of about 65 \AA from one view of a helix of sufficient length.

Summary of Procedure

The images on which the three dimensional reconstruction was based were obtained from cysts fixed for 1 h in 2 per cent glutaraldehyde (pH 7.4), washed overnight in cacodylate buffer and post-fixed in Dalton's chrome-osmium¹³, embedded in 'Epon'-'Araldite', sectioned and positively stained with lead citrate. The electron micrograph used in the three dimensional reconstruction was carefully chosen. This choice was based on criteria of orientation, contrast and order assessed by visual inspection of the image and, more important, of its optical diffraction pattern. The selected image was enlarged together with a calibrated density wedge onto fine grain film. The absorbance of the film was measured at regularly spaced points on a grid and converted, by means of intermediate emulsion calibration measurements, to a stain density by the amplitude contrast formalism⁸. In the computational process an individual helix was masked from the array of helices by an aperture. The stain density of the surrounding aperture was set equal to a constant value matching the density found on the perimeter of the helix. This procedure was found necessary in order to minimize the perturbing effect of the aperture on the calculated diffraction pattern. This masked helix was then Fourier transformed by the fast Fourier trans-

* The phases calculated from one "one sided" helix on the second layer line were symmetrical about the meridian. This is not considered significant for the phases from a "one sided" helix do not necessarily obey the symmetry relationships of a "two sided" helix. To a first approximation, the front half of a helix contributes to the Fourier transform on one side of a layer line while the back half of the helix contributes to the other half of the layer line. Thus when one examines the symmetry about the meridian along a layer line one is in effect comparing the transform of the front with the transform of the back of the helix. In a "one sided" helix one side or the other is not present and no comparisons can be made.

form algorithm of Cooley and Tukey¹⁴; it was necessary, however, to measure the stain density on a sufficiently fine grid to keep the aliasing error† small.

The formalism of Klug, Crick and Wyckoff¹² was used in carrying out the Fourier-Bessel inversion portion of the reconstruction. Because of the presence of an odd number of units per helical repeat it was possible to determine the contribution to each layer line of two Bessel terms of different order. Layer lines 0-17 inclusive were included in the reconstruction. The densities obtained from the Fourier-Bessel inversion emerged most naturally in cylindrical coordinates. These were converted to cartesian coordinates. Because one contour line adequately represented the data, 'Styrofoam' sheets were cut from templates made from the computer printout. A three dimensional model was made by gluing the 'Styrofoam' sheets together (Figs. 6a and b).

The magnification was calibrated by recording images of the 25 \AA spacing of indanthrene olive¹⁶. From images of calibrated magnification and known orientation the average of seven helical repeat distances was 1260 \AA .

Description of the Structure

A close inspection of images of the chromatoid body revealed that the lead stain was not continuously distributed throughout the specimen but existed as aggregates about 50 \AA in diameter. This was shown quite dramatically in stereo pairs of micrographs. Whether these grains were formed during the staining process or as a result of damage to the specimen in the electron beam is not known, but is being investigated.

The optical diffraction patterns of images of helices stained with lead are regular—although there is a high level of noise—to reciprocal spacings of $1/65 \text{ \AA}^{-1}$. This indicates that the lead grains are preferentially distributed on the average with a positional accuracy of about 40 \AA . There are several reasons for the relatively high noise level in positively contrasted, sectioned material compared with that in negatively contrasted images: the sectioning process frequently distorts structures, and consequently their diffraction patterns; larger lead grains exist in stain aggregates than are found in common negative contrast media; variations in section thickness can result in the splitting of layer lines.

A limiting factor in this analysis is that our sections were approximately 400 \AA thick whereas the diameter of the helix is 600 \AA . This detracts from the data and consequently from the certainty with which the peripheral regions of the helix are reconstructed. The correctness of a three dimensional structure reconstructed from a

* Cooley and Tukey used, to advantage, redundancies appearing in the Fourier transformation and greatly reduced the necessary computation time. Without their algorithm, the very large amount of data processed here would have been prohibitively expensive to transform at present day computer speeds.

† In doing numerical computations one must evaluate the continuous Fourier transform by means of sampling the continuous density at regular points of a grid, that is, a discrete Fourier transform. The difference between the continuous Fourier transform and the discrete Fourier transform is called the aliasing error¹⁵. There is in addition another error caused by the shape of the illuminating spot of the densitometer, $s(x,y)$. Taking both errors into account, one measures the absorbance $c(x,y)$ averaged over the spot shape, that is, $\int c(x+u, y+v) s(u,v) du dv$, at regularly spaced points on a grid which can be represented by a periodically spaced array of delta functions, $d(x,y)$. The Fourier transform of this is, by the convolution theorem, $[F(h,k)S^*(h,k)] \circ D(h,k)$ where $F(h,k)$ is the Fourier transform of $c(x,y)$, $S(h,k)$ is the Fourier transform of $s(x,y)$, $D(h,k)$ is the Fourier transform of $d(x,y)$ and \circ represents the convolution operation. This expression adequately approximates the continuous Fourier transform, if, first, $S(h,k)$ is essentially constant over the region of interest of $F(h,k)$ —that is, $s(x,y)$ is sufficiently localized—and second, if the peaks of $D(h,k)$ are separated by at least twice the reciprocal space distance at which $F(h,k)S^*(h,k)$ vanishes—that is, the sampling points are spaced close enough together.

sectioned helix is reflected in the degree to which the Fourier transform obeys correct phase relationships along layer lines*. Thus Fig. 3 provides an indication of the approximations involved in using sections less than one helix diameter thick. A second method of assessing this error is to compare structures reconstructed from images of partial helices sectioned through different regions. Fig. 5a and b demonstrate the type of agreement found among structures reconstructed from different helices. The helix from which Fig. 5a is derived was sectioned through the middle two-thirds of the helix while Fig. 5b is derived from a helix sectioned through the front two-thirds of the helix. Both are compared with the same overlay representing the best fit to the two structures and both agree quite well with the overlay.

The three dimensional structure of the chromatoid body helix consists of relatively discrete units (Fig. 6). The boundaries between units are in general well defined, but certain boundaries are indistinct. A principal region of contact of neighbouring units is at a radius of 100–200 Å from the helical axis. At this radius there is a region of density linking each unit with the neighbouring unit at the lower left (when the helix is viewed perpendicularly to the helical axis) and upper right. This contact accounts in a large part for the grooves perpendicular to the (1,5) direction which are so evident in Fig. 2c. The contact perpendicular to the (1,5) direction vanishes at radii greater than 200 Å and the resulting separation of neighbouring units causes the prominent groove perpendicular

* The helical selection rule for a sectioned helix is a weakened version of the selection rule for the intact helix. For an intact helix, on any layer plane only the Bessel functions given by the n,l plot for the helix can contribute to the Fourier transform of the helix. For a sectioned helix, however, density at a given radius from the helical axis is distributed in one, or two, allowed angular regions. The effect of this is that the correct n,l plot for a particular radius of a sectioned helix is now the n,l plot of the intact helix convoluted with a function which is just the Fourier transform of the function which has the value unity at angles where the helix is present and zero where the helix has been removed. The n,l plot of a sectioned helix will exist at each value of n,l permitted by the selection rule for an intact helix. These major values of n,l will be accompanied by smaller satellite values of n',l . The Fourier-Bessel inversion should reduce the contributions from the satellites. In a structure reconstructed from a helix which is about 75 per cent intact the satellite n',l peaks could be expected to contain about 25 per cent of the intensity contained in the n,l term from an intact helix. The Fourier-Bessel inversion can be expected to reduce the contributions from the satellite peaks to about 10 per cent of the total n,l intensity.

Fig. 4. *a*, A computer filtered, truncated "two sided" helix. Stain is represented by darkness. *b*, The three dimensional structure obtained from the helix in *a*, when embedded, sectioned, and projected as described in the text is shown as a contoured overlay on the filtered image. Note that shading within a contour indicates a lower density region. Also the helix has been stretched by a factor of two in the direction of the helical axis.

to the (3,2) direction. A second, although much smaller contact may exist at a radius of 150 Å, which connects each unit with its neighbours at the upper left and lower right (once again when viewed perpendicularly to the helical axis). A complex invagination which is roughly parallel to the helical axis is seen in some of the units on the left of the helix in Figs. 6 and 7. This cleft enters into the particle as deeply as 140 Å and breaks through to the edge of the particle at several places. It is a narrow feature (about 60 Å wide) but it appears consistently in the structures which were reconstructed and we think it is not an artefact. A slightly different choice of density could result in changes in the width of the cleft and in the location of its entrances and exits from the particle. Any interpretation of the structure will depend on the staining mechanism. It is thought that nucleic acids are stained

Fig. 5. A transverse sampling of the stain density map calculated from images of two differently sectioned helices. Stain is dark. *a* is the structure calculated from a helix longitudinally sectioned through the middle two-thirds of the helix and *b* is the structure calculated from a helix longitudinally sectioned through the front two-thirds of the helix. Both sections sample parts of the three different ribosomes (labelled 1, 2 and 3). The helical axis passes through the centre of the figures and is perpendicular to the plane of the page. The ripple shown by the arrow is an artefact which arises when one helix is masked from an array of interlocked helices. The ripple lies just outside the maximum radius of the helix.

Fig. 6. A stereo pair of a 'Styrofoam' model six-seventeenths of a repeat long that represents the distribution of stain in the helix. The diameter of the helix is 600 Å.

by lead citrate more strongly than proteins¹⁷. Whether the invaginations and low density regions are holes or non-staining areas is not clear.

Both negatively contrasted images and shadowed specimens of individual helices³ suggested that the helix was right-handed, although this identification is not yet complete. An inversion of the order of the 'Styrofoam' sheets along the helical axis in Fig. 6 gives the left-handed model.

Any test of a structure rests ultimately on the comparison of the structure and the image from which the structure was obtained. The signal to noise ratio in images of the chromatoid body was so low that a direct comparison was difficult. Two different types of structural checks were carried out.

From micrographs of thin sections of known orientation (Fig. 1) it can be shown that in "one-sided" helices in which the peripheral region of the helix is intact one sees long grooves perpendicular to the (3,2) direction. Similarly, in areas in which the peripheral regions of a helix are missing (truncated helices) the long grooves mostly disappear whereas short grooves perpendicular to the (1,5) direction are intensified. This is shown more clearly by the optically filtered image in Fig. 2c. At position A in Fig. 2c the long grooves are present whereas at position B the short grooves predominate. This agrees with what we observe in the reconstructed model if the peripheral region of the helix is intact in region A and cut off in region B. Thus there is the correspondence we expect between the reconstructed model and both the optically filtered image and the unfiltered image.

A second check was made by comparing two numerically processed images. The first calculated image, shown in Fig. 4a and in a stretched version in Fig. 4b, was obtained without imposing helical symmetry by filtering the image of a two-sided helix in the direction of the helical axis to remove noise. The second calculated image, shown as an overlay in Fig. 4b, was obtained on a computer by mathematically embedding the reconstructed model helix in a matrix of uniform stain density matching the background density at the perimeter of the helix. This structure was then mathematically sectioned and projected onto a plane. The two images agree very well.

This is strong evidence for the correctness of our three dimensional structure.

Relationship of the Chromatoid Body Unit to Ribosome Structure

As already indicated the asymmetric unit of the chromatoid body helix has not been shown to be a ribosome or even a ribosomal subunit. Nevertheless, because indirect evidence leads us to suspect a relationship between the chromatoid body unit and the ribosome, we compare information concerning the unit with available information about the ribosome, fully realizing that this comparison may be premature.

Fig. 7. A diagrammatic representation of the three dimensional structure of the chromatoid body helix. One entire helical repeat is shown.

Elliott's GX3 rotating anode

X-ray diffraction equipment includes an exclusive fine focus cathode system with a rotating anode of high power loading capability. 7 kW/mm² (actual area) is available with one thousand hours filament life. The plant includes the rotating anode tube mounted on a robust console which houses the vacuum system, cooling system and all controls. Tube current and voltage are stabilised within $\pm 0.1\%$. Focal spot sizes are easily interchanged without disturbing the filament and advanced long-life seal design ensures trouble-free operation from the dynamically balanced anode.

Simple to use—unique patented design in acrylic and nylon with sintered plastics bed support.

Minimal dead space with low-volume connections. Diameters selected to produce cross-sectional area of 2, 4, 8, & 16 sq. cms. Fixed or adjustable columns with or without jackets.

Standard lengths of 30, 60 and 90 cms.

Columns easily lengthened by joining.

Prompt delivery of standard columns from stock.

Preparative columns with bed volumes up to 50 litres are available to special order

Prices from £5

Astronomy

Edited by

SIR BERNARD LOVELL

*Nuffield Radio Astronomy Laboratories,
Jodrell Bank, Cheshire, England*

A collection of exact reproductions of the
seventy Astronomical Discourses delivered at
The Royal Institution of Great Britain between
1857 and 1939.

In two illustrated volumes. 6 x 9 ins. 836 pages. 1970

Price: £10 per set (available only as a complete set)

In the period covered by these Discourses, from 1857 to 1939, man's understanding of the universe was transformed. When Nasmyth lectured in 1864 he described the scene which would present itself to a spectator on the moon. Nasmyth's dream picture materialised 105 years later and it is indeed impressive to compare this with the astronauts' description of the scene.

This collection of the astronomical discourses makes fascinating reading. The historic figures of the past recreate themselves and their subject—Kapteyn, Milne, Eddington, Jeans and Slipher on the Universe, Huggins on spectroscopy, A. S. Herschel on the great Leonid meteor showers, Lockyer and Schuster on solar eclipses, the Earl of Rosse on the moon's heat, and the succession of Astronomers Royal from Airy to Spencer Jones all appear in these pages.

Reported dimensions of the 70S ribosome from *Escherichia coli* vary from 140 Å to 190 Å for negatively contrasted images¹⁸⁻²⁰, from 160 Å to 210 Å for positively contrasted images^{18,19} and from 170 Å to 200 Å for metal shadowed images²¹. *Entamoeba invadens* ribosomes have, however, been found to be somewhat larger than those of *E. coli*². Also, recently small angle X-ray studies in solution²² and physical studies²³ have shown that 30S, 50S and 70S ribosomes are larger in solution than when they are observed by electron microscopy. These recent results correspond to a particle in better dimensional agreement with our structure. Sectioned, positively contrasted crystals have been shown in many studies^{11,24} to preserve dimensions whereas negatively contrasted crystals frequently exhibit smaller dimensions than those indicated in X-ray diffraction studies. We have been unable to find any part of the structure which is reminiscent of the cap-like 30S ribosomal subunit observed by Huxley and Zubay¹⁸ or Hall and Slayter²¹, although the cleft which is observed in the structure may represent a partial division between a 50S and a 30S subunit. The dimensions of one unit (roughly 360 Å × 200 Å × 190 Å) correspond reasonably well with those given by Hill, Thompson and Anderegg²² for 70S *E. coli* ribosomes (400 Å × 200 Å × 135 Å).

We thank Optronics International, Inc., of Burlington, Massachusetts, for the use of a scanning densitometer, Dr R. Morgan for supplying a culture of *Entamoeba invadens*, Drs D. L. D. Caspar and C. Cohen for comment, and the Harvard Computation Center for assistance. This research was supported by grants from the US National Institute of General Medical Sciences and from

the Division of Research Facilities and Resources, US National Cancer Institute. J. A. L. acknowledges the support of an NIH post-doctoral award.

Observation of Formation of Deep Water in the Mediterranean Sea, 1969

by
MEDOC GROUP*

Temperature, salinity and other measurements taken from six research vessels are discussed with regard to the formation of deep water.

Previous Indications of Deep Convection

DURING the first three months of 1969, six research vessels belonging to France, Italy, the United Kingdom and the United States were engaged in a detailed study of the winter-time formation of deep water in the northern portion of the West Mediterranean Sea. In order to describe in time and space a quickly evolving oceanic phenomenon, a fairly dense set of measurements is necessary—which accounts for the need for several ships working together. In the past there have been occasional winter-time hydrographic sections which have shown evidence of deep convection. For example, the Mediterranean Atlas¹ shows a section (number 13) made by RV Atlantis in February 1961 with a narrow region in which the vertical stability appears to be much reduced;

but of course with a single section it is impossible to know whether the section actually passes through the centre of the phenomenon, and whether the process is beginning or ending. As another example, during January–March 1963 the French naval vessel Originy made repeated observations on the 6° E meridian south of Toulon. During that winter—a particularly cold, but not very windy one—vertical homogenization of density at some stations occurred all the way to the bottom (2,500 m); but at nearby (5 miles) stations the density stratification was not markedly disturbed². Comparison of hydrographic sections made at weekly intervals showed that this phenomenon of small-scale patchy convection appeared in a week's time. After a full month of severely cold weather, the homogeneous water was encountered in more extensive portions of the section—up to 40 miles. The centre of the homogeneous region appeared to be about 40 miles south of Toulon.

These various indications of the presence of a very active vertically convective region south of Toulon provided the motivation for the joint work described here: a multiple ship operation in January–March 1969, which yielded an unusually complete picture of the process of formation and sinking of deep water in wintertime. It is the most completely documented example of the phenomenon of deep convection that we have anywhere in the ocean.

In any season the area is characterized by a large

cyclonic gyre and the stability of the density stratification is lower in the centre than on the rim. In winter we can distinguish three phases. The first is the *preconditioning phase*, when every year, winter surface cooling occurs in the area and reduces the stability of the surface layer everywhere, leaving very little reserve buoyancy in the centre of the gyre. Vertical mixing takes place in the surface layer, the system remains a distinctly three layered one: the fresh cold surface layer, the salty warm intermediate layer, and the medium salinity, cold deep layer. The maximum near-surface density in the centre of the gyre reaches or exceeds $\sigma_t = 29.00$. In 1969 the onset of the NW to N winds marked the beginning of a second phase: the *violent mixing phase*, in which a rather narrow region of deeply penetrative convection occurs in the centre of the gyre, but other regions of the gyre are only slightly perturbed. When the stormy period ceases, the mixed water sinks rather quickly and spreads out horizontally: the *sinking and spreading phase*.

The Preconditioning Phase

During January 1-11, the British hydrographic survey vessel HMS Hydra scouted the area in the northwestern Mediterranean shown in Fig. 1, and found at the surface a region of low temperature, high salinity, and high density extending in a long strip from about 50 miles south of the Gulf of Lions into the Ligurian Sea. In the vertical the water was everywhere gravitationally stable. Although there were two storms during January, when the Woods Hole vessel Atlantis II resurveyed the region of highest surface density surrounding 42°N 5°E during January 24-28, it found that no marked change had occurred. The vertical section of salinity shown in Fig. 2 was taken by Atlantis II (the location of the section is shown by line A in Fig. 1) on January 31-February 1, and exhibits the well known three superposed layers of water generally present in the Mediterranean year-round. The intensity of these contrasts is diminished toward the centre of the section, underneath the surface patch of high salinity, but there is vertical structure everywhere.

The Violent Mixing Phase

During the evening of February 3 the NW to N wind began to blow strongly, and persisted with occasional lapses for most of February (Fig. 5b). During February 4

and 5, for example, it blew with speeds of approximately 35 knots and wet-bulb air temperature as low as 3°C . Using conventional formulae for calculating air-sea exchange processes, and regular surface meteorological observations obtained at the Bouée-Laboratoire (point L in Fig. 1) the evaporation seems to have been as much as 2 cm/day. A vertical section of salinity and temperature (Fig. 3) taken (on line B in Fig. 1) after the storm had been blowing 6 days (February 10-11) shows that strong vertical mixing did indeed occur, but not uniformly over the entire section. The central vertically mixing region is 1,400 m deep with essentially uniform salinity and temperature³.

It appears from comparison of vertical profiles that the properties of this mixed layer can be accounted for by simple vertical mixing of properties previously present brought about by strong surface cooling, and some admixture of shallow surface waters blown in from the north. Why the central mixed region is so narrow (some 25 miles) is somewhat obscure. Observations by various cooperating ships indicate that after the storm ending on February 17 the mixing had penetrated nearly to the bottom and the mixing region extended in a narrow strip with its axis oriented parallel to the coast.

The geographical extent of the mixing region, as a function of time, is well shown by the area at the surface in which salinity exceeds 38.42 parts per thousand, this high salinity being a sensitive indication of the presence of intermediate water mixed up from below. Fig. 4 shows areas of the surface where salinity exceeds 38.42 parts per thousand at four different times. The area outlined by the quadrilateral (1) was fairly densely surveyed by Hydra in the period January 1-11; only at two isolated points (marked by +) was there such high salinity measured. At this stage there was essentially no mixed water present. The triangular and rectangular areas (2) were surveyed during February 3-12 by Charcot, Atlantis II, Discovery, Origny and Bannock. A region of salinity in excess of 38.42 parts per thousand was found as shown in the figure, centred at 42°N 5°E . The later survey of February 15-28 by Charcot, Atlantis II, Discovery and Bannock in the very irregular area (3) shows this same area, but also another high salinity area in the Ligurian Sea. The final survey by Charcot, during March 18-31 in area 4 (no

Fig. 2. Salinity on Atlantis II section A (January 31, 1969).

observations in the Ligurian Sea), shows that the high salinity is now completely gone; at one point—marked by the crescent—the surface salinity actually reached 38.42 parts per thousand, but did not exceed it. The expanding and contracting of these areas in time in the region south of Marseilles actually gives a cinematographic representation of the presence of the deep mixed layer where it reaches the surface. On the other hand, the region indicated in the Ligurian Sea exhibits higher temperatures and lower densities; the mixed layer there was not observed to exceed 500 m depth, and this did not appear to be a source of deep water.

At this time, a variety of water types was present in the strip, west of 6° E, ranging from $\theta = 12.78^\circ \text{C}$, $S = 38.420$

parts per thousand to $\theta = 12.90^\circ \text{C}$, $S = 38.450$ parts per thousand. The water type of higher potential temperature had a dissolved oxygen concentration somewhat exceeding 4.55 ml./l. This high oxygen serves to differentiate that mixed water type from water elsewhere in the same range of temperature and salinity (but lower oxygen), so that we can use it as a "tag" to show the remarkable process of sinking, spreading and breaking up of the mixed water during the last portion of February and late March.

The Sinking and Spreading Phase

Repeated profiles were run along 6° E by Atlantis II and Charcot to document the time history of the phenomenon. Fig. 5a is a time against latitude plane showing the

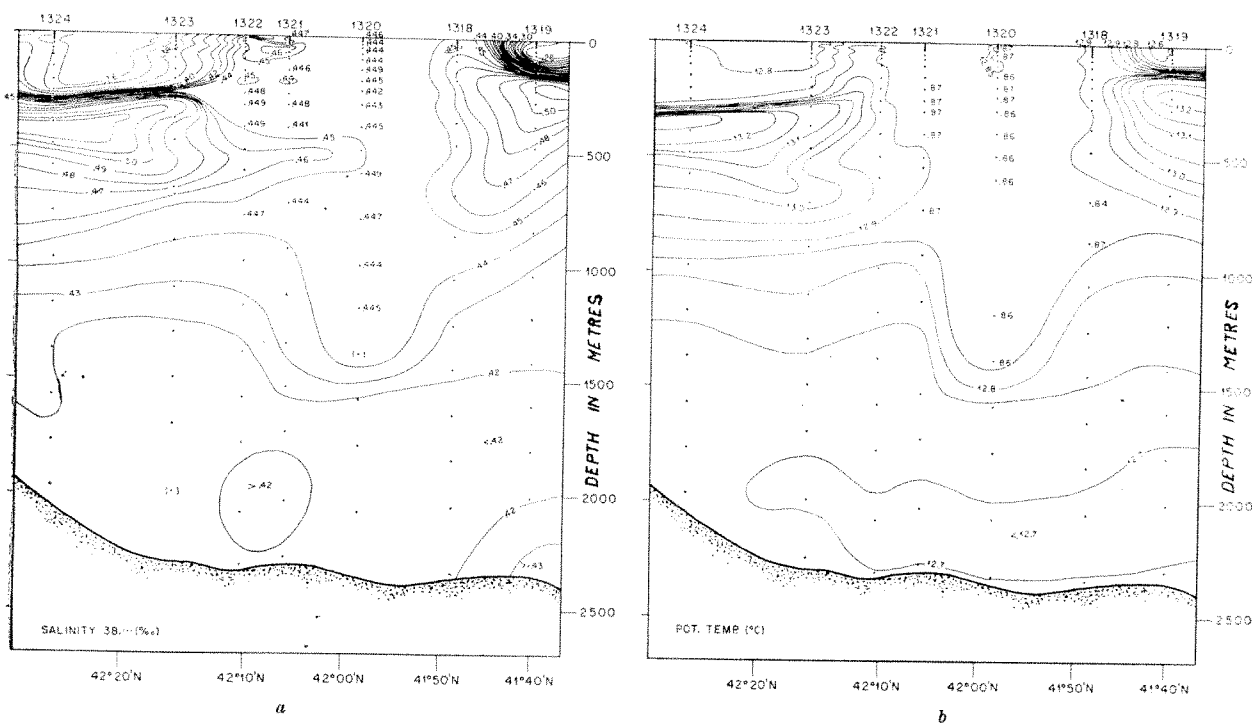

Fig. 3. *a*, Salinity on Atlantis II section B (February 10-11, 1969); *b*, potential temperature on same section.

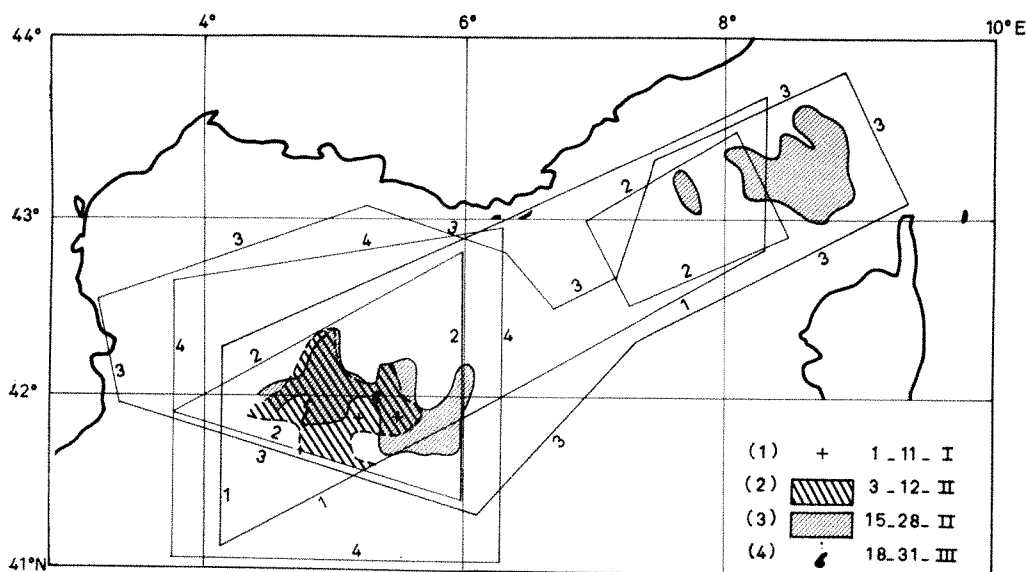

Fig. 4. Regions where surface salinity exceeds 38.42 parts per thousand during four different surveys. Total area of each survey also shown by numbered polygons.

positions of deep stations by the dots. Where there are no figures, there was no "tagged water" present. Elsewhere the figures indicate the depths (in hundreds of metres) bounding the "tagged water". Large amounts of "tagged water" are first observed on the second Charcot section (the first made after the storm): it extends from the surface to depths of up to 1,450 m, in a region about 30 miles wide, centred near 42° N. Subsequent profiles indicate sinking of the top boundary, but a fairly steady bottom boundary, and spreading north and south at about 2 miles/day. Fig. 6 shows the quite irregular geographical distribution of the "tagged water" during the Charcot survey of March 18–31, which suggests that the striated structure shown in Fig. 5a is not representative of the spatial structure of the advanced state of decay of the sinking process, but that many large fragments form.

The water type of lower potential temperature (see above) formed near 42° N, 5° E is probably very slightly more dense than the warmer variety and cannot be traced by its dissolved oxygen content. Below 1,000 m, however, its potential temperature and salinity were characteristically higher than those of the old deep water. An examination of vertical temperature profiles obtained on an expanded scale from the TSD probe used on board the Discovery shows that the spreading of the new deep water—as identified by anomalously high temperature—followed a pattern broadly similar to that of the new deep water at slightly less depth "tagged" by oxygen. Some of it evidently moved southwards from the region of violent vertical mixing at rates of at least 2 miles per day. In one place the vertical profile of potential temperature indicates that a layer of old deep water 700 m thick has been lifted upwards from 1,800 m to 1,000 m by an intrusion of new deep water.

The density of the violently mixed layer approaches

Fig. 5. a, Time against latitude diagram showing evolution of mixed water that is tagged by high oxygen. b, Simultaneous meteorological observations at the Bouée-Laboratoire.

Fig. 6. Charcot survey of March 18–31, 1969, showing geographical dispersal of tagged water.

that of the bottom water very closely, to within the accuracy of determination of density: ± 5 parts per million. The deepest penetration observed was at Discovery station 6844 on March 8, when it reached a depth of 2,430 m. Even in this case the bottom-most water remained distinguishable by its slightly lower temperature and salinity.

The Velocity Field

The RRS Discovery tracked twenty neutrally buoyant floats in the region near 42° N, 5° E, and set ten moorings each with three or four current meters. Three of the moorings were in place during the storms of February 12–16. Horizontal speeds were only slightly higher during the storm, and the spectrum of kinetic energy density shows a fairly uniform increase by a factor of about 2 at periods from 10 minutes to 10 hours. At longer periods, the motion appeared weak and disorganized until February 16, after the storm, when a definite eastward flow appeared. Floats revealed a cyclonic shear across the strip of dense mixed water, with eastward flow along its southern edge and westward to the north. By February 25 the mixed water had almost disappeared from the surface, and the predominant horizontal motions were similar to what might be expected of a field of eddies with diameter about 10 miles, tangential speeds decreasing downwards from about 15 cm/s at 10 m to 7 cm/s at 1,500 m, axes vertical, migrating irregularly at speeds of approximately 3 cm/s.

An isolated attempt by Atlantis II to measure vertical component of velocity in the mixed layer, using a neutrally buoyant float, rotated about a vertical axis by vanes, indicated at one time an upward vertical displacement of 800 m in 14 hours⁴.

There is an approximate equality between the amount of dense new water formed in the middle of the strip, and that seen later during March at depths around 2,000 m; it appears to have been enough to feed the entire Mediterranean outflow at Gibraltar for about 6 weeks.

This brief report is meant to convey the main results of the multiple ship operation; the detailed documentation will, we hope, appear in later papers written individually.

Geochemical Evidence for Ocean Floor Spreading in South Atlantic Ocean

The basal sediment layer on the flanks of spreading ridges should be enriched in iron and relatively poor in aluminium if present concepts of ocean floor spreading are correct^{1,2}. Recently published evidence from the third leg of the JOIDES expedition corroborates this hypothesis.

During this part of the expedition several stations were occupied at approximately 30° S and cores were taken at stations 14, 15, 16, 19, 20 and 21, between the Mid-Atlantic Ridge and South America. Rates of deposition, chemical compositions, water contents and densities were determined on the sediments from these cores³.

The reported results³ show that the ratio $Al/(Al+Fe)$, which has been useful in the delineation of anomalous sediments on spreading ridges^{1,2}, shows a distinct decrease with depth (see Fig. 1). The most intensively studied cores came from station 19; the results³ can be recalculated to show the accumulation rates for Al and Fe (see Fig. 2). The upper 100 m show normal pelagic accumulation rates, but in the lowest 40 m the accumulation rates for iron are anomalously high, resembling rates observed in recent sediments on the crest of the East Pacific Rise^{4,5}.

The evidence in Figs 1 and 2 strongly suggest that the formation of iron-rich crest sediments has taken place more or less uninterrupted since the middle Eocene, which is the age for the basal layer at station 19. The variations in thickness of the iron-rich basal layer may have resulted from the varying intensity in ocean floor spreading and volcanism or from intrusive basalt sills which would hide the true basement. Some of the undulations of the basement (see Fig. 1) are certainly also related to the fact that some stations (Nos. 20 and 21) are occupied on the Rio Grande Rise.

Fig. 1. Cross sections of sediments at about 30° S in south Atlantic Ocean. The number of the station is given above the figure and corresponding position (°W of Greenwich) below (for details see ref. 3). The ratio $Al/(Al+Fe) = 0.40$, is used to separate normal and iron-rich basal sediments. The lowermost part of the sediments locally have $Al/(Al+Fe)$ values less than 0.20.

Fig. 2. Accumulation rates of iron and aluminium in sediments from station 19.

Temperature Gradient above the Deep-Sea Floor

At sufficient ocean depths (several km) there is an increase of temperature with depth corresponding to the adiabatic lapse rate $\Gamma \approx 10^{-6} ^\circ\text{C}/\text{cm}$. Toward the bottom, the gradient becomes increasingly superadiabatic, because the water is heated from below by a geothermal heat flux H . Because H is small ($\sim 10^{-6}$ calories $\text{cm}^{-2} \text{ s}^{-1}$), only a slight superadiabatic effect is expected: $|dT/dz| < 2\Gamma$ at elevation $z > 1$ m. Measurements of hyperadiabatic gradients ($|dT/dz| = 10-1,000 \Gamma$) several metres, or even tens of metres, above the bottom have been reported¹⁻⁴, though it seems inconceivable that a strongly unstable layer several metres thick can persist. The experiment described here indicates that $|dT/dz| = 1.3 \Gamma$ at $z \sim 1$ m.

Critical Rayleigh number and Reynolds number considerations indicate that heat and momentum are transferred by molecular processes in a layer of thickness $h = 1$ to 4 cm just above the (smooth) sea floor⁵. Above this conductive layer there is convection. Townsend⁶ describes three regimes which he terms "forced", "mixed", "natural" (Fig. 1). For various elevations and typical shear stresses in the deep sea, Table 1 shows the predicted convection type and temperature gradient relative to the adiabatic gradient $-\Gamma = -1.2 \times 10^{-6} ^\circ\text{C}/\text{cm}$. The predicted slightly

superadiabatic temperature gradient contrasts with the reported measurements of hyperadiabatic gradients—for example, -15Γ to -65Γ in the layer $z=100-300$ cm (ref. 4). My initial measurements in this layer likewise indicated hyperadiabatic gradients ($\sim -100\Gamma$), but these were found to be caused by sensor self-heating and are thus spurious. Design changes have eliminated this “anemometer effect”⁷, and the ambient gradient has been measured.

Five Hewlett-Packard quartz-crystal temperature sensors were mounted on a frame and connected to a Snodgrass recording capsule⁸. With the frame standing on the sea floor, three of the sensors (I, II, III) were fixed at elevations 150 cm, 150 cm and 10 cm; two sensors (IV, V) were on a sliding vertical boom initially at elevations 290 cm and 150 cm, and after the boom was dropped, at 150 cm and 10 cm (see Fig. 2). The horizontal separation of the sensors was 10 cm. To soften the “boom-drop”, drag flaps were deployed at the boom top and a sponge-faced plate was attached to the bottom.

This arrangement allowed an *in situ* relative calibration of the sensors. The recorded time series were first converted to degrees Centigrade using laboratory calibrations. Then averages were computed for 1 h just before and another just after the boom-drop. It was assumed that two sensors at the same level should give the same average reading, any difference being calibration error which can be removed by a uniform additive correction to one or other series. In this way, all the other sensors were calibrated *in situ* relative to one upper fixed sensor (I) chosen as a “standard”. Calibration corrections from before and after the boom-drop were possible for the other upper fixed sensor (II). These corrections differ by only 1 part in 10^3 , implying that 1 h is, (i) an averaging time long enough to eliminate the random effects of small-scale turbulence, and (ii) an interval short enough that sensor drifts are unimportant.

The apparatus was dropped at $31^\circ 02' N$, $119^\circ 48' W$ (depth 3.7 km). The sampling interval was 1 min and the least-count resolution $1.7 \times 10^{-5}^\circ C$. After settling on bottom, the drag flaps were deployed. A day later, the boom was dropped. After another day, the apparatus was recalled to the surface for recovery.

A similar apparatus with a camera was placed within 2 km of this location on a previous occasion⁹. The topo-

Fig. 1. Theoretical relations for the mean potential temperature gradient within the benthic boundary layer. $H=H/c_p q$; $\tilde{\alpha}=ga$; $L=2.5 u_*^2/\tilde{H} \tilde{\alpha}$. (There is doubt that the relation given for “natural” convection is correct.)

Fig. 2. Temperatures recorded near the deep-sea floor; at elevations $z=10, 150, 290$ cm until boom-drop, thereafter at the two lower levels only.

graphy in the area appears to be uniform, so it is reasonable to suppose that the 3 cm sediment penetration and the smooth bottom, indicated in those photographs, also apply to this experiment. Simultaneous with this drop, and within 0.5 km of its location, a current direction time series was recorded with a second Snodgrass capsule.

Fig. 2 shows the corrected temperature records for the 2 h period centred on the boom drop. The current direction record from the adjacent capsule indicates that during this period the flow past the sensors was directed towards the instrument frame so the influence of the frame on the temperature records should have been slight. It is immediately apparent from the figure that temperature decreases with elevation, as expected. The mean gradients, implied by the corrected 1 h averages from just before and after the boom-drop, are given in Table 2. These values indicate $|\overline{dT/dz}|=1.3\Gamma$ in the layer $z=10-290$ cm. This agrees well with the theoretical predictions of Table 1; however, there are two surprises.

The theory predicts that temperature difference between 10 cm and 150 cm should be about four times that between 150 cm and 290 cm. But the measured differences are approximately the same. (It may be that the boom-drop, though gentle, disturbed the sensors slightly. A shock-induced change in the sensor crystal frequency of just 1 part in 10^8 could account for this result.)

In Fig. 2, the lower temperature difference vanishes briefly four times, and the upper difference (recorded only until boom-drop) vanishes once. At a later time (not shown) during a tidal reversal of current direction, the record shows isothermal conditions persisting for 3 h.

Does the metal frame act as a thermal "short-circuit" to the water flowing by? Rough calculations indicate that conductance through the vertical frame members and their associated boundary layers is insufficient. But the flow past these members has a Reynolds number of only 10^2 to 10^3 , so it may be a quasi-steady separated flow with trapped eddies enclosing the sensors in the wake¹⁰. Thermal "shorting" of these eddies might be achieved and an isothermal profile would then be indicated. If this is correct, then the brief isothermal incidents in Fig. 2 presumably occurred during momentary current reversals.

I thank Frank Snodgrass and Jim Irish for help with this work which was supported by the US Office of Naval Research.

Planetary-type Waves in the South West Indian Ocean

SOUTH of the latitude of the Cape of Good Hope, the Agulhas Current Stream (or at least most of it) turns back into the Indian Ocean and forms a zonal current called the Agulhas Return Current, whose mean axis of flow is approximately 38° – 39° S. Near the start of its eastward flow, the Agulhas Return Current has been shown to undergo sharp changes of direction (Fig. 1a). These deflections are apparent in the analysis made by Dietrich¹ and Le Pichon². The latter shows them occurring down to the depth of the salinity maximum and draws attention to the important influence of bottom topography. They are also very evident in the study made by Darbyshire³ of data from the cruises of SAS Natal and RS Africana II, occurring in three out of the four seasons examined. The deflections all occur near a prominent topographical feature, the Agulhas Plateau, and their recurrence suggests that they are a quasi-stationary feature and possibly planetary waves caused by the rapid changes in water depth. An investigation into this possibility has been made by comparing the flow patterns deduced from hydrological data with those predicted by theory.

The theoretical model we used was developed by Porter and Rattray⁴ for zonal flow over meridionally oriented topographical features, of a frictionless, steady (and initially uniform) barotropic current. Using the beta-plane approximation, they found a solution in

terms of the transport stream function and based on the conservation of potential vorticity. The obvious departure of this model from the baroclinic, non-uniform, time dependent, real ocean was emphasized by the authors.

The Agulhas Return Current seems to approximate to zonal flow over some meridionally oriented topography. It has, however, strongly baroclinic features so that close agreement between theory and observation is not to be expected.

We used Porter and Rattray's equations (8) and (11) for the calculations, together with the following data: width of the Agulhas Plateau = 260 km; initial depth, H = 5,000 m; depth over the Plateau = 3,000 m; depth immediately down stream of the Plateau = 4,200 m (for other depths and distances see Fig. 1c); value for beta in beta-plane approximation = $1.8 \times 10^{-8} \text{ km}^{-1} \text{ s}^{-1}$; initial velocity to the east, U , (assumed to be about the maximum barotropic velocity) = 10 cm/s.

Bathymetric data was taken from charts prepared by the South African Hydrographic Office and by Simpson and Forder⁵, and an approximate profile drawn for depth along 39° S. (Fig. 1c). The simplified profile from which the computational data were obtained is indicated by a broken line.

The predicted flow pattern is shown in Fig. 1b, where the normalized stream function — UHy/ψ is plotted against the zonal distance in degrees longitude. A chart of the surface dynamic isobars with reference to the 1500 db surface was drawn for intervals of 1 dynamic decimetre (Fig. 1a). Data from the following cruises were used: SAS Natal, 1962⁶; RS Africana II, 1962⁷ and 1961⁷; and RV Anton Bruun, 1964⁸. The first two cruises were almost synoptic and formed part of Darbyshire's³ study. All stations were occupied in the month of July or within a few days of it. The choice of the reference level was dictated by the limiting depth of key stations rather than by any conviction that it was a level of no motion—which it almost certainly is not. Where, because of the sparseness of stations, the contouring became especially subjective, the contours have been marked with broken lines. Light shading has been used to show the 4,000 m, and heavier

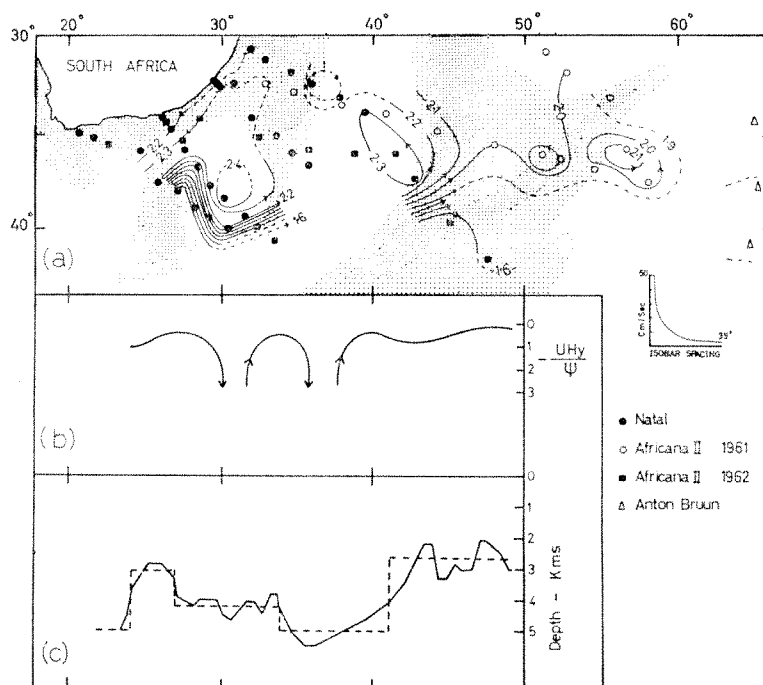

Fig. 1. a, Dynamic topography, 0/1,500 db, in dynamic metres. Bottom contours at 3,000 and 4,000 m have been shaded. b, Calculated normalized stream transport function for the barotropic mode. c, Section along 39° S showing approximate bottom topography (—) and simplified profile (---) used in the calculations. Horizontal scales for a, b and c are the same.

for the 3,000 m, water depths. Most of the essential features of the dynamic isobars are confirmed by the pattern of near surface isotherms.

Comparison of Figs. 1a and 1b which have similar horizontal scales shows that over the Agulhas Plateau both current patterns exhibit an equatorward tendency, which immediately downstream of the Plateau gives way to a sharp poleward and then equatorward deflection. The computed pattern has a phase lag which can be theoretically ascribed to the simplified form of bathymetry used. Its amplitude is, however, quite unrealistically large; although relatively large amplitudes are to be expected because the width of the Agulhas Plateau approaches a half wavelength.

Further downstream, the computed flow again deflects sharply poleward and then equatorward. The large deflection here (it is actually infinite) is caused by the increase in depth at about one wavelength distant from the Plateau. There are unfortunately no comparable hydrographic data available for this region.

Finally, over the western slope of the Madagascar Ridge both flow patterns show an equatorward deflection.

Noteworthy features indicated by the dynamic isobars are the northward branching currents, which seem to separate from the main Agulhas Return Current near the maximum equatorward deflections of the meanders. These branching currents are particularly conspicuous over the Madagascar and Indian Ridges and agree well with surface current charts based on ships' drifts¹⁰. Lacombe¹¹ and Le Pichon² have noted this tendency.

It seems that in the South West Indian Ocean there is a gyre on the west side which has an eastern limit in the region of 60°–70° E. In this vicinity, the zonal flow of the Agulhas Return Current appears from the dynamic topography to be much diminished.

Although the limitations of the dynamic topography method and the severe restrictions imposed on the mathematical model require caution in interpreting the flow patterns, it is clear from this comparative study that there are quite striking similarities between the baroclinic and barotropic modes in the Agulhas Return Flow. It is concluded that the bottom topography may well be a contributory influence on the direction of flow of this current and could account for the deflections near the Agulhas Plateau. The Agulhas Return Current provides a good opportunity for these conclusions to be tested more rigorously.

I thank Mr J. N. Marshall for very useful discussions on the computations and the Division of Sea Fisheries for making RSA Africana II data available.

Effect of Adhesive Tape on the Velocity Profile of Water

I REPORT here an interesting discovery, made while investigating velocity profiles close to a solid boundary. The experiments were carried out in a 5 inch channel of square section filled with water to a depth of 4.5 inches. Total head and static head tubes constructed of hypodermic tubing (0.020 inches outside diameter; 0.010 inches inside diameter) were used to measure the head by means of a 0.5 inch water gauge transducer of differential transformer type. Experiments were performed in a region of fully developed turbulent flow in order to discover the effect on the velocity profile of roughening the channel bed by sticking sand grains of various known dimensions to it by means of double-sided 'Scotch-Tape'.

Fig. 1. Velocity profiles. ●—●, Perspex channel bed (smooth); ●---●, 'Scotch-Tape' coated with sand 0.0035–0.0059; ○—○, 'Scotch-Tape' alone; ×---×, 'Scotch-Tape' coated with sand 0.0336–0.0472.

For the larger grains of sand it was necessary to assume that the lowest point on the profile lay at half the total diameter of the head tube plus half the mean height of the roughness from the channel bed, giving the profile shown (in Fig. 1). All the velocity distributions exhibited straight lines in semi-logarithmic plots indicating typical turbulent profiles consistent with those associated with surface roughness. The fine grain sand on the 'Scotch-Tape' gave a profile which approximated to the smooth surface profile.

Out of curiosity a profile was obtained for bare 'Scotch-Tape'. When plotted, this gave the results shown in Fig. 1, which imply that the tape is physically 'sticky' towards the water; that is, the tape exhibits a 'roughness' or 'stickiness' similar to that of a roughness of mean height 0.040 inches.

Microstructure of Hydrated Portland Cement Pastes

THE microstructure of calcium silicate hydrate pastes and normal portland cement, with a water to cement ratio of 0.5, has been investigated by transmission electron microscopy using Pt/C replicas. One of our chief aims was to gain a better understanding of the physical and mechanical properties of portland cement, properties thought to be affected decisively by microstructure.

It was believed that vital steps in the formation of the final microstructure of portland cement would be best revealed by studying the pure components, various combinations of these, and portland cement. For this reason the formation of the microstructure during the hydration of C_3S and C_2S paste was studied in great detail. Samples were examined following increasing times of hydration from 5 min to 6 months. One aspect of the study was to observe the effect on morphology of the admixtures, triethanolamine and calcium lignosulphonate. Another involved the etching, with glycol, of the surface of 6 month old samples of cement and C_3S and C_2S hydrated pastes to expose the underlying microstructure. Comparison was made with natural tobermorite treated similarly. Progress of the hydration reactions and the effects of etching were also followed by X-ray and electron diffraction.

Previous work has shown that the hydration products of portland cement are semi-crystalline fibres appearing as bundles, aggregates and sheets¹⁻⁷, but the relation between growth fabric and final microstructure of the hardened paste has not been clearly defined. Cleaved tabular masses observed in old cement pastes have generally been identified as calcium hydroxide. The present study indicates that the morphological evidence for this conclusion was insufficient, and that the microstructure of these platy-looking products is complicated.

In pastes of calcium silicates and portland cement, with a water to cement ratio 0.5, the initial products of hydration are amorphous-looking thin foils and fibrous particles. These products appear mainly on the surface of calcium silicate grains and grow to fill void spaces. The fibres bridge unhydrated grains and form an interlocking mesh,

Fig. 1. Electron micrograph of hydrated tricalcium silicate paste, water to cement ratio 0.5, age 1 month. Pseudomorphs surrounded by radiating fibrous hydration products intersecting at approximately 60 degree angles and merging into plates.

Fig. 2. Electron micrograph of hydrated tricalcium silicate paste, water to cement ratio 0.5, age 6 months. Platy hydration products, etched with glycol, display fibrous structure and pseudohexagonal morphology.

often meeting at an angle of about 60 degrees to form approximate isosceles triangles. Space between fibres becomes filled in with poorly crystalline hydration products composed of either a lime-rich form of calcium silicate hydrate or calcium hydroxide. Diamond⁴, using the scanning electron microscope, found that C-S-H material is encapsulated by lime or lime-rich amorphous material.

The final forms of the main hydration products are plates with marked cleavage. These frequently have a pseudohexagonal morphology, resulting from the triangular disposition of the felted fibres of calcium silicate hydrate. Surfaces of the plates often reveal the underlying fibrous structure (Fig. 1). The material that fills in space between fibres is generally more susceptible to etching by glycol than the fibres themselves (Fig. 2). It is this relation between the initial products that appear as fibres and thin sheets and the final tabular, massive structure that this paper will attempt to establish.

In the early stages of hydration, unhydrated grains of cement or calcium silicate are readily identified. When hydration is nearly complete the unhydrated grains seem to be replaced by pseudomorphs of no particular morphology (Fig. 3). These may well be of composition similar to the material that fills the space between the interlocking fibres. Cementitious material between cement pseudomorphs or grains of partly hydrated calcium silicate consists of tabular masses of platy C-S-H (Fig. 3). Because of its morphology and cleavage this has commonly been regarded as $Ca(OH)_2$.

This evidence that the C-S-H material has varying forms and morphology, and even different response to etching by glycol, leads to the conclusion that hydration products cannot be regarded as separate crystalline phases of fixed stoichiometric chemical composition but rather as solid solutions of calcium silicate hydrates and calcium hydroxide. This is in agreement with the conclusions presented by Taylor⁶ and Grutzeck and Roy⁸ showing that the Ca/Si ratio varies within the hydrated product. Morphological evidence that the hydration products are of poor crystallinity is supported by X-ray and electron diffraction data.

Fig. 3. Electron micrograph of hydrated tricalcium silicate paste, water to cement ratio 0.5, age 6 months. Main hydration product has massive tabular structure showing strong parallel cleavage. These tabular masses interconnect pseudomorphs of hydrated grains.

The morphological form of calcium silicate hydrate found in hydrated cement was the same as is present in the products of hydration of monomineral pastes. The hydrated cement is, however, much more complex because of its more variable composition.

From the standpoint of the mechanical properties of hydrated cement, the microstructure of the cementing system is really a composite material in which the fibrous network is imbedded in an amorphous material. It should provide very good mechanical properties and may well reflect the high compressive strength of the dense (low porosity) hydrated cement. It would be expected that the tensile strength of such a composite would also be high. In practice, however, it generally attains only one-tenth of the compressive strength. The work now presented shows that the masses of the cementing material appearing as tabular structures are not usually interconnected with each other but rather with areas representing original unhydrated grains (pseudomorphs, for example). Thus what might be considered interparticle connexions must be defined as material that seems to lack the reinforcement of the fibres.

This note summarizes some of the more important findings of a large-scale study and further details will be published later.

BIOLOGICAL SCIENCES

Molecular Structure of 1-Methyl-4-thiouracil-9-methyladenine: Unusual Base Pair in tRNA

4-THIOURIDINE is a constituent of the tRNA of *Escherichia coli*¹⁻³. It is located in a position where, according to the cloverleaf model, specific base pairing by hydrogen bonding is assumed not to occur. X-ray crystallographic⁴ and spectral analyses⁵ of the monomer and polymer nucleoside have been performed and 4-thiouridine is the first pyrimidine nucleoside that has been shown to exist in a *syn* conformation in the crystalline state. We now report studies on the molecular structure of the 1-methyl-4-thiouracil-9-methyladenine complex.

We obtained yellow prismatic crystals by evaporating an aqueous solution of an equimolar mixture of the two components at room temperature. The space group, cell dimensions and density of these crystals were P1; $a = 5.777 \text{ \AA}$, $b = 12.499 \text{ \AA}$, $c = 16.481 \text{ \AA}$; $\alpha = 91.98^\circ$, $\beta = 103.98^\circ$, $\gamma = 36.94^\circ$; $\rho_{\text{obs}} = 1.442$, $\rho_{\text{calc}} = 1.457 \text{ g/cm}^3$ ($Z = 2$). We collected about 1,900 data on a Siemens four circle diffractometer (Ni-filtered Cu radiation, 2θ , ω scan mode) and corrected them for geometrical factors. The non-linearity of a Wilson plot suggested that the structure was layered. The phase problem could not be solved by application of Sayre's equation or the heavy atom method for the atoms are not evenly distributed within the unit cell and from symmetry requirements the S-S interaction is not prominent in a vector map. The structure was finally solved by superposition methods and packing considerations. After two cycles of isotropic and anisotropic and full matrix superposition methods and packing considerations. After least squares refinement, the R -factor ($R = \sum |F_o| - |F_c| / \sum |F_o|$) was found to be 8.7 per cent for the 1,344 significant reflexions ($F_o = 3.0 \sigma_{F_o}$). At this state of refinement the following features are clear.

The molecular geometry of 1-methyl-4-thiouracil and 9-methyladenine is comparable with that published for 4-thiouridine⁴, 3'-acetyl-4-thiothymidine⁶ and the 9-methyladenine-1-methylthymine complex⁷. The uracil derivative is in the keto, keto form: the C2-O2 and C4-S bond distances (1.20 Å and 1.65 Å respectively) are indicative of double bonds. The atomic arrangement of the heterocyclic rings and their substituents is nearly planar. The deviations of the substituents from the heterocycle least squares planes are less than 0.1 Å. The angle between the least squares planes of the uracil and the adenine residue in one base pair is about 5.0° .

Fig. 1 shows the crystal packing of the 1-methyl-4-thiouracil-9-methyladenine complex. The molecules are layered nearly parallel to the b , c plane at $a = 0$. The distance between adjacent layers is about 3.3 Å. The sulphur atoms of the uracil residues and the methyl groups of the adenine residues form a hydrophobic region along the a , b plane at $c = 0$. In the less hydrophobic region around $c = 1/2$, hydrogen bonds involving nitrogen and oxygen, but not sulphur, are formed. The links in a 1-methyl-4-thiouracil-9-methyladenine base pair are hydrogen bonds between N6(A) and O2(U) (2.86 Å) and between N7(A) and N3(U) (2.94 Å). The 9-methyladenine molecule is connected with its symmetry related partner by a N6(A)-N1(A) (3.00 Å) hydrogen bond.

All the crystalline adenine-uracil or adenine-thymine complexes so far investigated display the Hoogsteen type of base pairing with hydrogen bonds from adenine N6 and N7 to uracil O4 and N3. The Watson-Crick type of base pairing (adenine N6 and N1 to uracil O4 and N3) has not been observed^{7,10}. A "reversed" Hoogsteen base pairing involving uracil O2 and N3 instead of O4 and N3 has been found in this structure and in adenine-5-bromouracil complexes^{8,9}. The inductive effect of the bromine atom in the latter structures was presumed to be responsible for a less electronegative proton acceptor uracil O4 atom⁸.

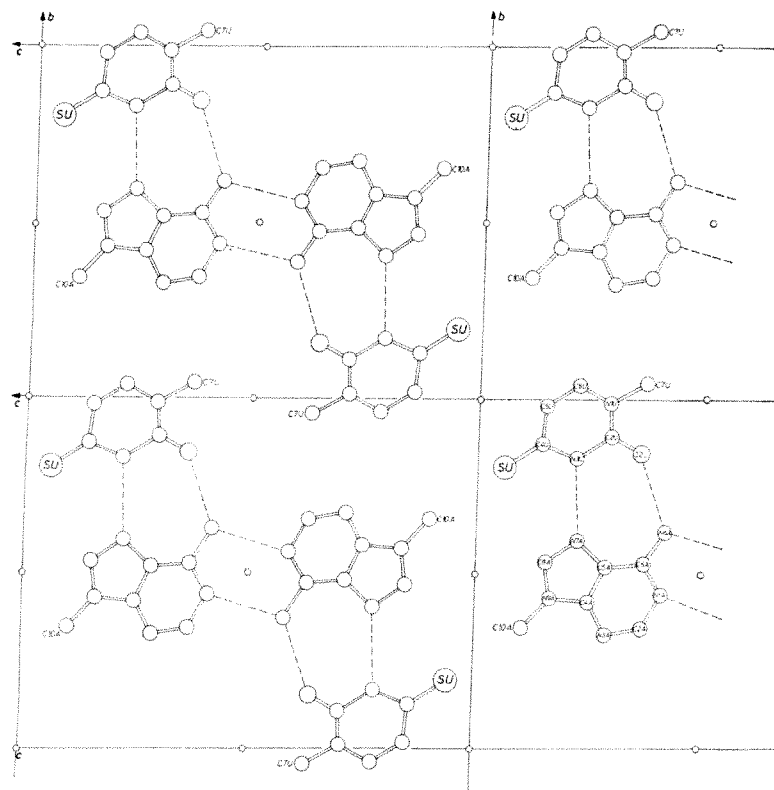

Fig. 1. Packing diagram of the 1-methyl-4-thiouracil-9-methyladenine complex projected down a^* .

This is, however, not the only effect which determines the geometry of these complexes, for in the 1-methyl-5-bromouracil-9-methyl-adenine base pair the regular Hoogsteen scheme applied¹¹. One would assume therefore that in the 1-methyl-4-thiouracil-9-methyladenine complex, the formation of a hydrogen bond involving uracil O2 instead of S4 is favoured for two reasons. The sulphur atom is less electronegative than the oxygen atom, that is, the $\text{NH} \cdots \text{S}$ hydrogen bond is weaker than an $\text{NH} \cdots \text{O}$ bond¹²; furthermore, the packing arrangement might require this type of hydrogen bonding.

We thank Professor F. Cramer for his interest and support and Professor D. Mootz, Universität Braunschweig, for making available his Siemens diffractometer.

structure³ and function^{4,5} of nucleic acids. Its use is, however, complicated by the fact that it also deaminates the adenine and guanine residues in nucleic acids^{6,7}. Guanine, the reaction of which is least desirable for mutagenic purposes, is usually the base most reactive to nitrous acid⁸. In addition, nitrous acid causes the formation of nitro compounds⁹, the cross-linking of DNA (ref. 9), the destruction of guanine residues¹⁰, and other side reactions which diminish its usefulness.

We recently reported that sodium bisulphite can be used to deaminate cytosine derivatives, by the route illustrated in Fig. 1 (ref. 11). The cytosine derivative is converted quickly by sodium bisulphite, at pH 5, to an addition compound which readily deaminates, on standing, to the corresponding uracil addition compound. The latter is converted to uracil by adjustment of the pH to 9, and removal of excess bisulphite. Adenine and guanine derivatives do not react in these conditions. We now wish to report the successful application of this procedure to the specific deamination of the cytosine residues of yeast RNA.

To a solution of 5.0 mg of sodium yeast ribonucleate (Schwarz BioResearch, Orangeburg) (purified by HCl precipitation at 5° C, and washing with ethanol and ether) in 0.5 ml. of H_2O was added 118 mg of NaHSO_3 . The pH was adjusted to 5 by addition of concentrated HCl, and the reaction was allowed to proceed as indicated in Table 1.

The pH was then adjusted to 9 with 1 M NaOH. The RNA was separated from the bisulphite by chromatography on 'Sephadex G-25M' (Pharmacia, Piscataway). For analysis of composition, the RNA was hydrolysed at 37° C with 10 ml. of 1 M KOH for 24 h. The solution was neutralized to pH 6.5 with HClO_4 , cooled at 4° C for 16 h, and the precipitated KClO_4 was removed by filtration. The nucleotide mixture was then fractionated on a column of Amberlite 'CG-400' resin (formate), using an exponential gradient in formate (for details see ref. 12). The column is capable of resolving the four major natural ribonucleoside 2'-(3')-phosphates, as well as inosine 2'-(3')-phosphate and xanthosine 2'-(3')-phosphate. The peaks eluted were identified by their position and by their R_f (thin-layer chromatography) in a solvent made of 13.8 g $\text{NaH}_2\text{PO}_4 \cdot \text{H}_2\text{O}$ dissolved in 900 ml. of H_2O . The pH of this solvent was adjusted to 6.8 with H_3PO_4 , the volume was diluted to 1,000 ml. with H_2O , and 200 g of $(\text{NH}_4)_2\text{SO}_4$ and 20 ml. of 1-propanol were added. The R_f values observed for the 2'-(3')-phosphates of adenosine, guanosine, uridine and cytidine, respectively, were 0.31, 0.52, 0.76 and 0.80. The quantitative amounts of each

Fig. 1. Deamination of cytosine derivatives by bisulphite

Specific Deamination of RNA by Sodium Bisulphite

THE ability of nitrous acid to deaminate the cytosine residues of nucleic acids to uracil has made it valuable both as a mutagen^{1,2} and as an aid to studies of the

peak eluted from the column were determined by a spectrophotometric method¹².

The results of four deamination runs, in various conditions, are summarized in Table 1. No new reaction products were observed, and all of the adenine and guanine nucleotides were recovered (within experimental error). A varying amount of deamination of the cytosine residues of the RNA to uracil was observed. An initial portion of the cytosines reacted rapidly. The rate of reaction then slowed down, and finally levelled off when 90 per cent of the cytosines was deaminated. This is not surprising, considering the heterogeneous nature of yeast RNA. It suggests that the reactivity of cytosine residue to bisulphite is strongly influenced by the secondary structure of the RNA. The altered composition of the RNA in run 4 was reflected in its ultraviolet spectrum. The ratio A_{280}/A_{260} for the deaminated RNA (pH 2) was 0.44 ($\lambda_{\max}=258$) whereas the corresponding ratio for the starting RNA was 0.62 ($\lambda_{\max}=260$).

Table 1. ANALYSIS OF BISULPHITE-MODIFIED RNA

Run	Conditions	Nucleotides isolated (mmoles $\times 10^3$)				Deamination of Cp (per cent)
		Cp	Up	Ap	Gp	
1	Unmodified RNA	2.3	3.1	2.8	3.2	
2	15 h, 25° C	1.3	4.3	2.5	3.1	45
3	24 h, 37° C	0.75	4.8	2.5	3.2	68
4	84 h, 37° C	0.20	5.2	2.7	3.3	91
5	168 h, 37° C	0.21	5.7	2.9	3.4	92

The abbreviations Cp, Up, Ap, and Gp refer to the 2'-(3')-phosphates of cytidine, uridine, adenosine, and guanosine, respectively.

Preliminary experiments with DNA confirm the dependence of cytosine reactivity on nucleic acid secondary structure. In the conditions of run 5, the cytosines of single stranded phage F₁ DNA were completely converted to uracils, while those of double stranded calf thymus DNA were essentially unreacted. Thus sodium bisulphite should be of value for the chemical modification of nucleic acids, and may replace nitrous acid in many of its uses.

This investigation was supported by a grant from the US Public Health Service. We thank Professor Peter Model of the Rockefeller University for a gift of phage F₁ DNA.

Inhibition of Vaccinia Virus Growth by 1-Methyl-4-aminopiperazine

RIFAMPICIN inhibits the replication of poxvirus^{1,2}; experiments with other rifamycin derivatives suggested that the hydrazone side-chain of rifampicin was essential for its antiviral activity³. We describe here the action of the characteristic component of this side-chain, 1-methyl-

4-aminopiperazine, and compare it with that of the other analogue of rifampicin, 3-formylrifamycin SV (FSV), and another compound, 1-methyl-4-benzylidenaminopiperazine, which contains the hydrazone side-chain but not the rifamycin moiety.

The activities of these drugs, together with twenty-seven other rifamycin derivatives, were screened by plating eighty plaque forming units (p.f.u.) of various viruses on primary cultures of chick embryo fibroblasts. After the adsorption period, the cell sheet was overlaid with nutrient medium in agar containing 800–100 μ g/ml. of each drug. With vaccinia virus, methylaminopiperazine and methylbenzylidenaminopiperazine completely inhibited plaque formation at 200–300 μ g/ml. The second drug was slightly toxic to the cells at 800 μ g/ml. At twice the limiting dose of toxicity, none of the drugs inhibited plaque formation by fowl plague, Newcastle disease, pseudorabies and herpes type 2 viruses. Some of the drugs were highly toxic: the cells did not stain with neutral red after 4 days' treatment with 50–100 μ g of 4-benzylidendi-azo-4-deoxyrifamycin S (BDS), the O-benzoyloxime of 3-formylrifamycin SV (BOF), 4-(1-methyl-2-imidazolin-2-ylidiao)-4-deoxyrifamycin SV (MID) or 1'-benzyl-2'-methyl-3'-acetylpyrrolo-(3,2-C)-4-deoxyrifamycin SV (BAP).

In cells treated for 1 h with 200–400 μ g/ml. of these compounds ¹⁴C-uridine incorporation was inhibited by 90 per cent, and the incorporation of a hydrolysate of ¹⁴C-protein was only reduced by 40–50 per cent. Methylbenzylidenaminopiperazine also inhibited uridine incorporation but its action was more easily reversed by washing the cells; methylaminopiperazine had no effect. Similar results were obtained when *in vitro* transcription with sonicated nuclei was investigated (Table 1).

Although the activity of polymerase aggregate was not influenced by methylaminopiperazine in the assay mixture *in vitro*, treatment of whole cells with methylamino-

Table 1. ACTION OF VARIOUS INHIBITORS (400 μ g/ml.) ON INCORPORATION OF ³H-UTP INTO ACID PRECIPITABLE MATERIAL OF SONICATED NUCLEI FROM CHICK EMBRYO FIBROBLASTS

	Incorporation (d.p.m.)	
	Number	Per cent of control
No drug	1,424	
BDS	348	24
MID	191	13
FSV	1,508	106
Rifampicin	1,291	90
Methylaminopiperazine	1,928	135
Methylbenzylidenaminopiperazine	178	12
BAP	522	36
BOF	624	44

The components of the assay mixture were added in the following order: (a) 0.7 ml. of a solution containing 80 μ moles of Tris-HCl (pH 8.6), 3.5 μ moles of MgCl₂, 1 μ mole each of CTP and GTP, 2 μ moles of ATP, 0.1 μ mole of UTP, 5 μ moles of phosphoenolpyruvate and 0.01 M mercaptoethanol; (b) 400 μ g of one inhibitor; (c) 2 μ Cl (corresponding to 0.0013 μ mole) of ³H-UTP and 20 μ g of pyruvate kinase; (d) 0.3 ml. of sonicated nuclei obtained from 8×10^7 cells, according to the method of Bach and Johnson⁴. After incubation for 30 min at 37° C, trichloroacetic insoluble radioactivity was determined by standard procedures.

Table 2. ACTION OF METHYLAMINOPIPERAZINE ON WHOLE CELLS AND ON BROKEN CELLS

	Incorporation of ³ H-UTP by sonicated nuclei (d.p.m.)	
	Number	Per cent of control
No inhibitor	2,898	
Methylaminopiperazine (800 μ g/ml.)		
(a) On suspended whole cells, for 2 h at 37° C	928	32
(b) On suspended whole cells, for 30 min at 37° C	522	18
(c) On suspended whole cells, for 30 min at 0° C in distilled water	456	16
(d) On broken cells, immediately after treatment with the Dounce homogenizer	2,745	95
(e) On the enzyme aggregate, in the assay mixture before addition of ³ H-UTP	2,650	95

5×10^6 Embryo fibroblasts were suspended in Eagle's medium without calcium and with 0.5 per cent glutamine plus 2.5 per cent calf serum. The suspension was divided into six aliquots which were agitated for 2 h at 37° C; samples (a) and (b) were treated with the drug for 2 h and the last 30 min, respectively. All the samples were then centrifuged and the sediments collected in ice-cold distilled water. The drug was then added to sample (c); after 30 min at 0° C and treatment with 0.25 per cent Triton X-100, the cells were disrupted with six strokes of a Dounce homogenizer and the drug was added to sample (d). The nuclei were isolated, sonicated, and assayed for polymerase activity as in Table 1. In one mixture (e), the drug was added just before ³H-UTP.

piperazine before preparation of the nuclei extract resulted in the suppression of transcription activity of this extract; the effect was lower after 2 h than after 30 min of treatment at 37° C, an indication of the transient presence of the drug in its active form (Table 2). The drug seems not to prevent the synthesis of polymerase but, rather, to bind to some component (polymerase?) during the preparation of the nuclear extract. A similar inhibition of transcription was obtained, whether the cells were pre-incubated for 30 min at 37° C with the drug, or whether they were only in contact with the drug when they were allowed to swell in distilled water for 30 min at 0° C. By contrast, the "site" susceptible to methylaminopiperazine was apparently no longer available when the structure of the cell was destroyed, for addition of the drug after homogenization with the Dounce apparatus did not cause any inhibition of transcription.

Methylaminopiperazine did not inhibit *in vitro* RNA synthesis by 2 units of *E. coli* RNA polymerase in the presence of 100 µg/ml. thymus DNA. By contrast, BDS (4 µg/ml.) inhibited this reaction by 73 per cent; BOF and MID also had some activity. Methylbenzylidenaminopiperazine was not active on the bacterial polymerase, although it inhibits transcription by the enzyme aggregate from chick embryo fibroblasts.

We now return to the action of methylaminopiperazine on vaccinia virus replication. Its effect in liquid medium, on several cycles of growth, is smaller than that described for solid medium. After treatment for 21 h with 200, 50 and 20 µg/ml. of methylaminopiperazine, the virus titres were 24, 40 and 100 per cent of the controls, respectively. Inhibition of virus growth, however, was 86 per cent if three doses of 20 µg/ml. each were given to the cells at 6 h intervals. The action of the drug thus seems transient.

Because of the reversibility of the action of methylaminopiperazine, the time of its action was shown in the

Fig. 1. Single-step growth cycle of vaccinia virus in monolayer of chick embryo fibroblasts, with 1 h pulse treatments by 500 µg/ml. methylaminopiperazine. Unadsorbed virus was washed from all the cultures 3 h after the addition of virus; each 1 h treatment with drug was also followed by washing and addition of fresh nutrient medium. A control series of cultures received no drug but received fresh medium at the same times. For all cultures, virus was titrated in the disrupted cells 12 h after addition of the virus. The points in the graph correspond to the 1 h drug treatment and are the means of three experiments, expressed in percentage of the virus titre for control cultures.

Fig. 2. Number and size of vaccinia virus plaques, with various concentrations of rifampicin (A), methylaminopiperazine (B) or methylbenzylidenaminopiperazine (C) in agar (—), or with these drugs plus 10 µg/ml. FSV (---). ○, Plaques of normal size; ○, small plaques; ●, minute plaques.

conditions of a single-step growth cycle (Fig. 1). The early and the late period of the cycle of growth are susceptible to a 1 h treatment with 500 µg/ml. of the drug, but the processes which take place 4 to 6 h after addition of the virus are completely resistant.

It was noted that FSV at low doses (10 µg/ml.) decreases the inhibitory effect of methylaminopiperazine, methylbenzylidenaminopiperazine and rifampicin on vaccinia virus plaques (Fig. 2).

HeLa cells were grown in suspension and infected with 10–20 p.f.u. of vaccinia virus per cell; cytoplasmic extracts were prepared 6 h later and assayed for polymerase activity with no DNA added; there was no ³H-UTP incorporation with cytoplasmic extracts from uninfected cells, and the activity of the viral enzyme, in the cytoplasm, was not inhibited by methylaminopiperazine; it was, however, completely blocked by BDS (Table 3, experiment 1). Thus the RNA polymerase bound to viral DNA is not completely masked, for it is susceptible to BDS, a drug which therefore seems to have a broad range of action: it has also been shown to inhibit both bacterial and animal cell polymerases.

Table 3. EFFECT OF INHIBITORS ON VACCINIA VIRUS RNA POLYMERASE PREPARED FROM CYTOPLASMIC FRACTION OF INFECTED CELLS

Expt.	Inhibitors added	Incorporation of ³ H-UTP (d.p.m.)
1	<i>In vitro</i> to the assay mixture	
	No drug	800
	BDS	0
2	To whole cells, 30 min before preparation of cytoplasmic extract	
	No drug	1,046
	Methylaminopiperazine	500

Cytoplasmic fractions were prepared according to Kates *et al.*¹ from HeLa cells infected for 6 h with vaccinia virus; the fractions were assayed for RNA polymerase activity as described in the legend to Table 1. In experiment 1, 400 µg/ml. of BDS or 800 µg/ml. of methylaminopiperazine were added to the assay mixture immediately before addition of ³H-UTP. In experiment 2, 800 µg/ml. of methylaminopiperazine were added to the cell suspension 5–5 h after infection with the virus; the drug was left in contact with whole cells for 30 min at 37° C before preparation of the cytoplasmic extract.

In a second experiment, HeLa cells infected with vaccinia virus for 5.5 h were treated with 800 µg/ml. methylaminopiperazine for 30 min at 37° C and the cytoplasmic fraction was then immediately prepared. In these conditions, the drug inhibited RNA polymerase activity of the fraction by 50 per cent (Table 3, experiment 2). Thus, like rifampicin⁶, methylaminopiperazine has no action on the *in vitro* activity of vaccinia virus RNA polymerase, but prevents at least partly its action when added to whole cells.

We then attempted to obtain mutants resistant to some of the drugs. Vaccinia virus was grown in liquid medium in chick embryo fibroblasts treated with 200 µg/ml. of methylaminopiperazine or methylbenzylidenaminopiperazine, 100 µg/ml. of rifampicin, or 20 µg/ml. of BDS or FSV. After three passages in the same concentration of drugs, the populations of viruses were titrated in the presence or absence of the corresponding drug in agar

Table 4. ASSAY FOR SUSCEPTIBILITY TO DRUGS OF VARIOUS VACCINIA VIRUS POPULATIONS GROWN FOR THREE PASSAGES IN THE PRESENCE OF DRUGS

Virus grown with	Titrated with the following drugs in agar (doses in $\mu\text{g}/\text{ml}$)					
	Methylamino- piperazine		Methylbenzylidenamino- piperazine		Rifampicin	
BDS	300	200	300	200	200	150
Rifampicin	0	25 s	0	20 s	0	25 s
Methylaminopiperazine	30 s	60 n	66 s	80 s	66 n	60 n
Methylbenzylidenaminopiperazine	40 s	70 s	40 s	100 n	66 s	50 s
No drug	0	28 s	0	18 s	0	20 s

Values represent percentage plaques calculated from the number of plaques obtained with no drug in the agar. s and n: plaques of small and normal size. Viruses grown with FSV or methylbenzylidenaminopiperazine showed similar susceptibilities as viruses grown with BDS or rifampicin, respectively.

(Table 4). The inhibition of plaque formation by methylaminopiperazine, methylbenzylidenaminopiperazine or rifampicin for viruses previously cultivated in the presence of BDS or FSV, was similar to that for the control viruses grown without drugs. By contrast, all three drugs in agar were less active on viruses cultivated with rifampicin, methylaminopiperazine, or methylbenzylidenaminopiperazine. Cloned stocks grown from thirty plaques did not prove to be clearly resistant to the drugs, however, by contrast with previous reports of rifampicin-resistant mutants². The results in Table 4 indicate, however, that virus populations with cross resistance to rifampicin, methylaminopiperazine and methylbenzylidenaminopiperazine can be obtained. Our other observations also support the hypothesis that methylaminopiperazine and rifampicin inhibit the replication of vaccinia virus by the same mechanism.

Compounds MID and BDS were synthesized by Dr N. Maggi (methods to be reported elsewhere). We thank Mr Léopold Tack and Jacques Stiénon for technical assistance.

Reversal of Anti-viral Effects of Rifampicin

RIFAMPICIN prevents vaccinia virus growth^{1,2} by a still undefined mechanism. Viral DNA and early and late species of messenger RNA are synthesized in the presence of rifampicin³⁻⁶; early and late viral proteins are also made, although synthesis of the latter declines sooner than in the absence of the drug^{3,4,6,7}. Rifampicin does not inhibit the RNA polymerase activity contained within purified vaccinia virus particles^{3,5,7-9}, but the drug prevents the formation of particulate RNA polymerase activity⁵. This enzyme can ordinarily be demonstrated, at late times in vaccinia-infected cells, after treatment of cytoplasmic fractions with mercaptoethanol and detergents¹⁰⁻¹³. Rifampicin has also been found to block vaccinia virus assembly during the formation of the viral envelope and preceding the appearance of virus particles^{6,14}. The sequence of events which follows the removal of rifampicin has now been examined in order to correlate

Fig. 1. The sequence of events following the removal of rifampicin. The number of membrane limited regions of viroplasm (envelope precursor membranes) were counted in 100 HeLa cell thin sections and compared with the total of coated envelope profiles formed after the removal of rifampicin. Cytoplasmic extracts were prepared by disrupting cells in 0.01 M Tris-HCl buffer, pH 8.6. The nuclei were removed by centrifugation at 500g for 2.5 min and the supernatant was treated with 0.05 per cent Nonidet P-40 detergent (Shell Chemical Co., New York) and 0.02 M dithiothreitol at 0°C for 30 min. RNA polymerase activity was measured by the incorporation of ³H-UTP into acid precipitable material⁵. The formation of ³H-thymidine labelled viral particles was determined as previously described⁶ in a separate experiment under similar conditions. The two points in the lower right are control values obtained when rifampicin was not removed.

the effects observed on the formation of the late particulate RNA polymerase activity and on the assembly of viral envelopes.

HeLa cells were treated with rifampicin (100 $\mu\text{g}/\text{ml}$) 10 min before infection with vaccinia virus (thirty plaque forming units/cells)³. After 8 h, the drug was removed by washing the cells three times with ice-chilled medium. The cells were then resuspended in warm medium (0 time) and the incubation was continued at 37°C. At intervals, samples were removed and rapidly chilled by pouring over crushed frozen medium. The cell pellet was fixed with cold glutaraldehyde and prepared for electron microscopy⁶. Total cytoplasmic RNA polymerase activity in another portion was measured by a procedure similar to that of McAuslan⁵.

Except for rare immature vaccinia particles, the only viral structures which could be defined by electron microscopy in the rifampicin treated cells consisted of numerous irregular membranes which surrounded portions of electron dense viroplasm^{6,14}. These irregular membranes were trilaminar, but lacked the outer spicule coat which is characteristic of poxvirus envelopes. The irregular membranes were direct precursors of virus envelopes as shown by the rapid appearance of transitional coated forms after removal of rifampicin¹⁴. Each precursor envelope structure seems to give rise to several coated envelopes⁶. Conversion of envelope precursor membranes to coated envelopes was almost complete within 10 min after rifampicin was removed, and the number of the latter rose dramatically during this time (Fig. 1). An appreciable increase in the late particulate RNA polymerase activity could not be demonstrated until after the rifampicin effect on the formation of the viral envelope was completely reversed (Fig. 1). The rise in polymerase activity was nearly coincident with the formation of DNA-containing virus particles isolated by sucrose density gradient centrifugation and may signify that integration into

particulate form is required before this enzyme activity can be detected.

Immunoglobulin Allotypic Determinants on Rabbit Lymphocytes

THE initiation of the immune response is believed to involve the recognition of antigen by specific receptors on the surface of lymphocytes. The transformation of rabbit and human lymphocytes by antisera to immunoglobulins¹⁻³, the blocking of antigen binding by lymphocytes using anti-immunoglobulins⁴ and the inhibition of antigen induced lymphocyte transformation by anti-light chain serum⁵ suggest that such receptors are immunoglobulin in nature or at least possess immunoglobulin determinants. We have now obtained direct evidence for the presence of immunoglobulin determinants on the surface of rabbit lymphocytes by autoradiography using radio-labelled anti-allotype sera.

Anti-allotype sera were raised against allotypes Ab4 and Ab5 by immunizing rabbits of one allotype with antibody of another allotype coated on to killed *Proteus vulgaris*⁶. The sera were monospecific with respect to the allotypes Aa1, 2 and 3 and Ab4, 5 and 6 as judged by gel precipitation. The IgG fractions of these antisera and of the sera of normal rabbits of allotypes Ab4,4 and Ab5,5 were obtained by chromatography on DEAE-cellulose in 0.03 M phosphate buffer (pH 6.5). Labelling of the IgG with ¹²⁵I was performed by the chloramine T method^{7,8}: 1 mCi of ¹²⁵I (specific activity 8-12 Ci/mg; Radiochemical Centre, Amersham: 'IMS4') was mixed with 500 µg of protein in phosphate-buffered saline (PBS) at room temperature and chloramine T added to a final concentration of 450 µg/ml. After 1 min the reaction was terminated by the addition of sodium metabisulphite at a final concentration of 1.2 mg/ml. Inorganic iodide and other low molecular weight products were removed from the iodination mixture by passage through 'Sephadex G25' previously equilibrated in PBS.

Peripheral blood was obtained from three rabbits of genotypes Ab4,4, Ab5,5 and Ab4,5. Red blood cells were sedimented in 3.5 per cent dextran 'T250' (Pharmacia) in 0.9 per cent saline at 37° C for 45 min. The leucocyte-rich supernatant was spun down at 150g and the cell

Fig. 1. Frequency distributions of grain density (grains/cell) on the lymphocytes from the homozygous Ab 4.4 rabbit. 1A, Treated with labelled anti-4; 1B, 1C and 1D, controls, see Table 1. Cells with a grain density greater than eleven were considered to be specifically labelled.

pellet washed three times in Eagle's medium at 4° C. Cell counts were performed conventionally in 2 per cent acetic acid and aliquots containing 2×10^6 lymphocytes obtained. Each aliquot was spun down and re-suspended in 0.25 ml. of iodinated antibody at a concentration of 600 µg/ml. in PBS for 30 min at 4° C. The details of specific and control incubations are shown in Table 1. After incubation with antibody the cells were spun down and washed four times in Eagle's medium at 4° C, and rich supernatant was spun down at 150g and the cell (40g, 15 min). The smears were fixed in methanol and dipped in a 1:4 dilution of Ilford 'K5' nuclear emulsion to give an approximate emulsion thickness of 2-3 µm. Slides were exposed for 20 days, developed in Kodak 'D19b' and stained with May-Grünwald-Giemsa. After coding the slides, grain counts on approximately 200 lymphocytes (100 for each of two slides) were performed for each of the numbered experiments.

Table 1. SPECIFIC AND CONTROL INCUBATIONS OF LYMPHOCYTES WITH LABELLED ANTIBODY

Cell genotype	Experiment	Reagents added
Ab 4,4	1 A	¹²⁵ I-anti-Ab 4*
	1 B	¹²⁵ I-anti-Ab 5
	1 C	Excess anti-Ab 4, then ¹²⁵ I-anti-Ab 4
	1 D	Excess Ab 4 + ¹²⁵ I-anti-Ab 4
Ab 4,5	2 A	¹²⁵ I-anti-Ab 4
	2 B	¹²⁵ I-anti-Ab 5
	2 C	Excess anti-Ab 4, then ¹²⁵ I-anti-Ab 4
	2 D	Excess anti-Ab 5, then ¹²⁵ I-anti-Ab 5
	2 E	Excess Ab 4 + ¹²⁵ I-anti-Ab 4
	2 F	Excess Ab 5 + ¹²⁵ I-anti-Ab 5
Ab 5,5	3 A	¹²⁵ I-anti-Ab 5
	3 B	¹²⁵ I-anti-Ab 4
	3 C	Excess anti-Ab 5, then ¹²⁵ I-anti-Ab 5
	3 D	Excess Ab 5 + ¹²⁵ I-anti-Ab 5

* Ab 4, anti-Ab 4 and so on refer to IgG fractions of specific allotype or antibody directed against allotypic determinants.

† Excess of Ab 4 and anti-Ab 4 and so on was ten-fold relative to labelled anti-Ab 4. Treatment of cells with unlabelled antibody preceded the addition of the labelled antibody by 30 min.

Lymphocytes showed specific labelling with the appropriate anti-allotype (experiments 1A, 2A, 2B and 3A), a wide range of grain densities being observed (Figs.1-4). There was some overlap with the results obtained in the controls and lymphocytes were only regarded as specifically labelled if the grain density exceeded that in the controls (see legends). In the homozygous rabbits the number of positively labelled lymphocytes was 83 per cent in the

Fig. 2. Frequency distributions of grain density on the lymphocytes from the heterozygous Ab 4,5 rabbit. 2A, Treated with labelled anti-4; 2C and 2E, controls, see Table 1 and text.

Fig. 3. Frequency distributions of grain density on the lymphocytes from the heterozygous Ab 4,5 rabbit. 2B, Treated with labelled anti-5; 2D and 2F, controls, see Table 1. Cells with a grain density greater than 11 were considered to be specifically labelled.

Ab4,4 animal (experiment 1A) and 72 per cent in the Ab5,5 animal (experiment 3A). In the heterozygous Ab4,5 animal 30–50 per cent of the lymphocytes labelled with anti-allotype 4 (experiment 2A), depending on the control baseline accepted, and 47 per cent with anti-allotype 5 (experiment 2B). The appearance in the light microscope suggested surface labelling of the lymphocytes and this was confirmed in a separate experiment by electron-microscopic autoradiography (Fig. 5a and b). Red cells, monocytes and the majority of polymorphs had grain densities within the range of control preparations. A few blast-like cells (less than 1 per cent of the total white cells) were heavily labelled. Comparable results were obtained with three further Ab4,4 rabbits where 91, 85 and 80 per cent respectively of the blood lymphocytes were specifically labelled with anti-Ab4.

The results are consistent with the existence on rabbit lymphocytes of membrane components having specific allotypic determinants. It is unlikely that the labelling observed was the result of phagocytosis or antibody secretion because experiments were carried out at 4° C. The fact that only 40–50 per cent of the cells were labelled in the heterozygote rules out the possibility of non-specific adsorption of IgG from the donor serum; if cytophilic antibody were present one would expect 100 per cent of the lymphocytes in the heterozygote to be labelled with each anti-allotype. Because approximately 85–90 per cent of

the serum immunoglobulins in the homozygote carry the *b* locus allotype⁸, our finding of these allotypic markers on 70–85 per cent of the lymphocytes makes it likely that nearly all peripheral blood lymphocytes in the rabbit will be shown to possess surface immunoglobulins. Thus the labelling of only 40–50 per cent of the lymphocytes in the heterozygote by each anti-allotype would suggest that individual cells carry only one allotypic marker. Direct evidence for allelic exclusion has been obtained in the case of plasma cells and splenic small lymphocytes using double-labelling immunofluorescent techniques (ref. 10 and unpublished results of B. Pernis).

Compared with other direct methods for demonstrating allotypic markers on rabbit peripheral blood lymphocytes, autoradiography seems to be the most sensitive. In our experiments up to 83 per cent of the lymphocytes were labelled, but not more than 50 per cent stain with fluorescent labelled anti-allotype (unpublished results of B. Pernis), and only 60 per cent form rosettes with anti-allotype-coated erythrocytes¹¹.

The percentage of mouse lymphocytes bearing surface markers is not as high as in rabbits. Raff *et al.*¹², using autoradiographic and fluorescent techniques, found that only 40 per cent of mouse splenic lymphocytes labelled with anti-IgG, although they noted a difference in the sensitivity of the two techniques; our own preliminary experiments using autoradiography are consistent with these findings in that only 55 per cent of mouse peripheral blood lymphocytes labelled with anti-light chain.

In these studies with rabbit lymphocytes, each grain corresponds approximately to 700 bound anti-allotype molecules assuming an efficiency of 50 per cent for iodination and 10 per cent for autoradiography. On this basis the number of anti-allotype molecules attached to each cell varied from 7,000 to more than 40,000. This implied variation in number of surface receptors per cell may depend on the immunoglobulin class, the age of the lymphocytes and perhaps their immunological function.

We thank Miss V. Petts for technical assistance, Mrs G. Stead for preparation of the manuscript and Dr A. S. Kelus for advice and anti-allotype reference sera. This

Effect of Diameter on the Electrical Constants of Frog Skeletal Muscle Fibres

THE relatively large electrical capacity of skeletal muscle fibres^{1,2} is generally attributed to the transverse tubular system which ramifies over the cross-section of the fibre and enlarges the effective area of the surface. From an analysis of the frequency dependence of the impedance, Falk and Fatt³ assigned a capacity of $2.6 \mu\text{F}/\text{cm}^2$ to the surface membrane and $4.1 \mu\text{F}/\text{cm}^2$ to the contribution of the tubules. Gage and Eisenberg⁴ showed that fibres "detubulated" by the glycerol method had a low frequency capacity of $2.1 \mu\text{F}/\text{cm}^2$ as compared with $5\text{--}12 \mu\text{F}/\text{cm}^2$ in normal fibres.

If the capacity resided wholly in the surface the quantity C_M (the apparent capacity per unit area of surface), would be expected to be independent of diameter. On the other hand, if the capacity were chiefly tubular in origin, C_M should increase linearly with fibre diameter provided current spreads to the middle of the fibre. The experiments described here were designed to test this prediction and to obtain more reliable estimates of the internal conductivity.

Single fibres were isolated from the sartorius or semitendinosus muscles of *Rana temporaria*. The diameter was determined by measuring the thickness in two directions at right angles at about seven points along the length used in the electrical measurements. Two microelectrodes were inserted; one applied rectangular current pulses lasting about 300 ms in inward and outward directions; the other recorded the electrotonic potential at varying distances from the current electrode. The method of analysis was similar to that used previously^{1,2,5}, except that allowance was made for the finite length of the fibres. The Q_{10} of the sarcoplasmic conductivity was 1.37 and of the membrane conductance 1.49, and these values have been used to correct for small variations in temperature between experiments. It was unnecessary to correct C_M since the Q_{10} of the capacity was close to unity.

Twenty-one isolated twitch fibres with diameters varying between 38 and 165 μm were measured at room temperature. The results (Fig. 1) show that the sarcoplasmic conductivity G_i did not vary with fibre diameter and at 20°C was $5.91 \pm 0.13 \text{ mmho}/\text{cm}$ (mean and s.e., $n=21$). By contrast, the low-frequency membrane capacity per unit area of surface increased from about $3 \mu\text{F}/\text{cm}^2$ at 40 μm diameter to about $10 \mu\text{F}/\text{cm}^2$ at 160 μm .

Optical measurements of fibre diameter are not reliable in whole muscle or in bundles of fibres. But because the experiments with isolated fibres showed that sarcoplasmic conductivity is independent of fibre diameter, a diameter can be obtained from the internal resistance per unit length and the mean value of the sarcoplasmic conductivity at the temperature of the experiment.

The upper set of points in Fig. 2 gives the low frequency capacity (C_M), measured with rectangular current pulses, as a function of diameter in fibres in the sartorius muscle or in bundles from the semitendinosus. The results, which are essentially the same as in Fig. 1, again show that C_M increases with diameter in an approximately linear manner. The average C_M of the fibre group with diameters between 120 and 139 μm was $8.5 \pm 0.19 \mu\text{F}/\text{cm}^2$ (mean and s.e., $n=19$) whereas that in the range 40 to 59 μm was $4.6 \pm 0.17 \mu\text{F}/\text{cm}^2$ ($n=9$).

The values of the membrane conductance G_M also in-

Fig. 1. Internal conductivity, G_i , versus fibre diameter (A), and low frequency membrane capacity, C_M , versus fibre diameter (B) in isolated twitch fibres. ●, Semitendinosus. ▲, sartorius. Experiments were carried out at 20° C.

creased with diameter, but the scatter of the values was greater than with C_M . The average value of G_M in the 120 to 139 μm group was 0.365 ± 0.018 mmho/cm² ($n=19$) whereas that in the 40 to 59 μm group was 0.213 ± 0.015 mmho/cm² ($n=9$). In a large fibre the tubules probably account for at least half the apparent membrane conductance (compare ref. 6) but the scatter of the results makes it difficult to assign a definite fraction to their contribution.

As have been pointed out by several authors⁷⁻⁹, the capacity can also be measured by determining the conduction velocity θ and the time constant τ_f of the exponentially rising foot of a propagated action potential. The equation for calculating the capacity is

$$C_f = \frac{DG_i}{4\theta^2 \tau_f} - G_f \tau_f \quad (1)$$

where D is the diameter, and C_f and G_f are the effective capacity and membrane conductance (in parallel) during the foot of the action potential. The second term on the right hand side is small compared with the first and can usually be neglected. At 21.5° C the average value of τ_f was 0.127 ms in twenty fibres with a mean diameter of 94 μm and a conduction velocity of 209 cm/s. The mean value of C_f derived from equation (1) was 2.56 $\mu\text{F}/\text{cm}^2$. As can be seen from the middle set of points in Fig. 2 the capacity obtained by this method is constant over the range of diameters from 56 to 141 μm .

To obtain "detubulated" fibres, bundles of muscle fibres were immersed in hypertonic Ringer fluid containing 400 mM glycerol for 1 h and were then returned to normal Ringer fluid for electrical measurements of the kind described here. The glycerol treatment either disrupts the tubules or disconnects them from the surface, and large molecules like ferritin or peroxidase can no longer enter the tubular system^{4,10-12}. Such fibres give no mechanical twitch but have fairly normal action potentials; their internal conductivity was found to be almost the same as in normal fibres.

The conduction velocity of fibres treated with glycerol was 60 per cent faster than normal, the average velocity in eleven fibres with a mean diameter of 90 μm being 341 cm/s; in these fibres the time constant of the foot of the action potential was 0.131 ms. The values of C_f calculated by equation (1), which are shown by the lowest set of points in Fig. 2, have a mean value of 0.9 $\mu\text{F}/\text{cm}^2$, in approximate agreement with the value of 1.2 $\mu\text{F}/\text{cm}^2$ obtained by extrapolating the low frequency capacity of normal fibres to zero diameter. The increase of conduction velocity is explained by the reduction of capacity associated with detubulation.

Experiments with rectangular pulses of current gave the low-frequency capacity of the same group of glycerol-treated fibres as 1.87 $\mu\text{F}/\text{cm}^2$ in fair agreement with Gage and Eisenberg⁴. One explanation of the difference between

high and low frequency capacities in these fibres is to attribute it to an imperfection in the membrane capacity¹³. Another is to assume that glycerol treatment does not, disrupt or disconnect the tubules completely.

The three curves in Fig. 2, which are a reasonable fit to the experimental points, were calculated from the theoretical model described by Adrian, Chandler and A. L. H.¹⁴. In this model, which was based on Falk and Fatt³ and Falk¹⁵, it is assumed that (i) the transverse tubular system is an open-mouthed regular network with a fractional volume (ρ) of 0.003 and a volume/surface ratio (ζ) of 10^{-6} cm (compare ref. 16); (ii) the conductivity of the luminal fluid (G_L) is 10^{-2} mho/cm⁻¹, that is, slightly less than the conductivity of Ringer fluid; (iii) tubular and surface membranes have identical properties, the capacity (C_W) being 1 $\mu\text{F}/\text{cm}^2$ and the conductance (G_W) 0.5×10^{-4} mho/cm²; these values were chosen to give an apparent membrane capacity and conductance similar to those found experimentally². In applying the theory to our results we used 0.9 $\mu\text{F}/\text{cm}^2$ instead of 1.0 $\mu\text{F}/\text{cm}^2$ for C_W ; the other constants were as proposed by Adrian, Chandler and A.L.H.

Curve 1 (low frequency capacity in normal fibres) is plotted from equation (22) of ref 14. Curve 2 (capacity from foot in normal fibres) is

$$C_f = \rho \sqrt{(\tau_f G_L C_W / 2\zeta)} \frac{I_1(a/\lambda_f)}{I_0(a/\lambda_f)} + C_W \quad (2)$$

where I_0 and I_1 are hyperbolic Bessel functions, a is the radius and λ_f is the space constant in the tubules of the exponentially rising voltage

$$\lambda_f = \sqrt{\left(\frac{G_L \zeta \tau_f}{2C_W} \right)} \quad (3)$$

Curve 3 (capacity from foot in glycerol-treated fibres) is

$$C_f = C_W = 0.9 \mu\text{F}/\text{cm}^2 \quad (4)$$

Fig. 2. Variation of capacity with diameter in twitch fibres. Curve 1, low frequency capacity in normal fibres. ●, Semitendinosus; ▲, sartorius. Experiments were carried out at 20° C. Curve 2, capacity during foot of action potential in normal fibres. □, Semitendinosus; △, sartorius. Experiments were carried out at 19.5° to 22.5° C. Curve 3, capacity during foot of action potential in detubulated fibres. Semitendinosus muscle was used at 20.0° to 21.8° C. The theoretical basis of the three curves is given in the text. The upper set of points includes the data from Fig. 1.

The physical basis of curves 1 and 2 is straightforward. From the values of ref. 14 it turns out that the space constant in the steady state is 100 μm , whereas the space constant for an exponentially rising voltage of time constant 0.13 ms is about 8 μm . Thus almost all the tubular network contributes to the low frequency capacity, but only the outer zone to the effective capacity during the foot of the action potential. The low frequency capacity therefore increases with diameter, but C_f is nearly constant for the range of diameters between 50 and 150 μm .

The general agreement between theory and experiment helps to validate the model of Adrian, Chandler and A. L. H., and provides strong evidence for attributing the high capacity of twitch fibres to the transverse tubular system. The estimates of tubular and surface capacity are in good agreement with those obtained from impedance measurements by Dr M. Schneider (personal communication).

Effect of Fatty Acids on Contractility and Rhythm of the Heart

SINCE the finding in 1961 that free fatty acids inhibit the myocardial oxygenation of glucose¹, increasing emphasis has been placed on the role of free fatty acids as myocardial fuel². It is now known that free fatty acids inhibit glucose metabolism at several sites³. In studies on the human heart *in situ* free fatty acids are the dominant fuel in the fasting state⁴. It has therefore been suggested that free fatty acids are of major importance as a source of myocardial energy.

But circumstantial evidence has grown up to suggest that free fatty acids can in certain circumstances be toxic to the heart. In patients with acute myocardial infarction those with the most free fatty acid in the blood are most liable to develop arrhythmias^{5,6}. In dogs with ischaemic lesions of the myocardium, an abrupt increase of the plasma free fatty acids as a result of infusion of heparin and a lipid emulsion is associated with ventricular extrasystoles and ventricular arrhythmias⁷. These effects are on pathological hearts, but we have tested the direct effects of fatty acids on cardiac contractility in normal isolated hearts.

Fig. 1. Effect of octanoate on the contractility of isolated perfused rat heart. When the substrate of the isolated rat heart is changed (marked by arrow) from glucose to 2.8 mM octanoate contraction abruptly decreases and a high-grade atrioventricular conduction defect develops after 3 min. Normal contractions resume 3 min after changing back to a substrate of 5 mM glucose.

Isolated rat hearts were perfused with a Krebs-Henseleit bicarbonate medium, pH 7.4, with 5 mM glucose, or medium chain free fatty acid (octanoate) as substrate. Cardiac contractility was monitored by an intraventricular latex balloon⁸. Octanoate was prepared from octoic acid (British Drug House, Poole, Dorset) which was more than 97.5 per cent pure octoic acid; the rest consisted of other medium chain fatty acids as shown by gas-liquid chromatography. There were no known toxic substances in the octoic acid.

Table 1. EFFECT OF OCTANOATE ON CONTRACTILITY AND HEART RATE OF ISOLATED PERFUSED RAT HEART

Concentration of octanoate (mM)	No. of observations	Peak systolic pressure (per cent)	Heart rate (per cent)
2.800	(4)	59	81
1.400	(4)	83	98
0.700	(2)	62	100
0.350	(1)	70	100
0.175	(2)	69	100

Peak systolic pressure and heart rate are expressed as percentage of values obtained with 5 mM glucose as the only substrate. Mean values with glucose were: peak systolic pressure, 50 cm of H₂O; heart rate, 214 beats/min (fourteen observations in each case).

When the substrate of the isolated heart was abruptly changed from 5 mM glucose to 0.175–2.8 mM octanoate, within 1–2 min the peak systolic pressure fell to 59–83 per cent of the value with glucose as substrate (Table 1). With the highest octanoate concentration (2.8 mM) the effects were: (i) the heart rate decreased; (ii) a 3:1 atrioventricular block developed and the peak systolic pressure decreased to one-third after 2–3 min in two experiments (Fig. 1) and (iii) after re-exposure to glucose the rhythm reverted to normal in one experiment (Fig. 1), while in another experiment partial reversal to normal occurred. When the perfusion with 1.4 mM octanoate was prolonged, an irregular rhythm (quadrigeminy) developed after 5 min in one of seven experiments. Prolonged perfusion with 0.7 mM octanoate resulted in no rhythm disturbance.

In other experiments the rate of oxidation of 1.4 mM sodium octanoate-1-¹⁴C was 4.2 ± 0.8 (means \pm s.e.m., four hearts) $\mu\text{mole of octanoate/g wet weight/15 min}$, while 0.3 ± 0.06 μmole were recovered in the tissue lipid fraction. When 2.8 mM octanoate was added to 5 mM glycose-U-¹⁴C, the rate of oxidation of glucose was reduced to 11 per cent of the control value (four hearts). Although contractility was not measured, no serious arrhythmias developed.

These experiments show that octanoate, a medium chain length fatty acid could decrease the contractility of the isolated perfused rat heart and could cause arrhythmias. No similar changes occurred with albumin-bound long chain free fatty acid (palmitate) in physiological concentrations^{8,9} nor were rhythm disturbances noted when both glucose and octanoate were present in the perfusate. The metabolic behaviour of labelled octanoate was similar to that of labelled albumin-bound palmitate.

Octanoate also inhibited the uptake of glucose and pyruvate by the perfused rat heart^{10,11}. When hearts were perfused with both glucose and long chain fatty acid, the formation of triglyceride was increased¹², probably accompanied by a decrease in the tissue concentration of free fatty acid. It is not, however, known whether glucose could encourage the formation of triglyceride from octanoate.

It is attractive to postulate that the accumulation of free intracellular fatty acid is toxic to heart function, for example, by inhibiting oxidative phosphorylation¹³. This could explain (i) the effect of a very high concentration of fatty acid (2.8 mM octanoate) on the heart; (ii) the decreased efficiency of contraction of the isolated atrium when exposed to 2 mM hexanoate as sole substrate¹⁴ and (iii) the effect of very high circulating concentrations of long chain fatty acids on the rhythm of the infarcted heart, because uptake of free fatty acid by the ischaemic segment is proportional to the circulating concentration¹⁵, while oxidation of free fatty acids is probably reduced on account of hypoxia². Furthermore, since completion of this report, high but not low perfusate concentrations of a long-chain fatty acid, linoleate, have also been shown to be toxic to the perfused rat heart¹⁶.

The experiments reported here show that fatty acids in high concentrations can be toxic to the normal heart and can result in decreased contractility and rhythm disturbances.

Electron Probe Microanalyser Localization of Lead in Kidney Tissue of Poisoned Rats

ATTEMPTS to explain the morphological changes of the kidney induced by lead poisoning have been concerned chiefly with nuclear and cytoplasmic inclusions^{1,2}. Cytoplasmic inclusions have been shown to contain Fe (ref. 1), but the composition of nuclear inclusions remains a subject for debate. It is still not clear whether lead is deposited within the kidney and some authors deny a direct action of this element in favour of a mechanism of indirect action through vascular changes³. Fortunately, the problem of detection of metallic localizations within the kidney is amenable to direct observations with the electron probe microanalyser, an instrument ideally suited to the purpose, with a detection limit of about 10^{-15} g and a spatial resolution of about $1 \mu\text{m}$ (ref. 4).

Kidney tissue was taken from Sprague-Dawley rats fed for 72 weeks on 1 per cent lead acetate solution⁵. Con-

Fig. 1. Electron beam scans of rat kidney tissue, showing location of lead, calcium and phosphorus. Accelerating voltage 35 kV, specimen current 10^{-7} A. Each scan covers the same area of $100 \mu\text{m} \times 100 \mu\text{m}$. a, Specimen current; b, lead; c, calcium; d, phosphorus.

ventional paraffin embedded sections were made, mounted on pure silicon wafers, and the paraffin removed by xylene. Such sections, about $20 \mu\text{m}$ thick, were suitable for pathological purposes. Numerous glomeruli and normal and dilated tubules could be clearly defined under the microscope. In the electron probe (CAMECA), lead was readily found within cortical tubules in granules of differing shape and size. Fig. 1 shows a typical localization within a kidney tubule. Notable concentrations of calcium and phosphorus were found to be associated with the lead. Other elements were probably also present, but the chief constituents of the granules were lead, calcium and phosphorus. The scanning X-ray images (Fig. 1) also showed that calcium and phosphorus, in contrast to lead, appeared weakly throughout the tissue comprising the tubules.

These observations lend support to recent electron microscope work⁵ which suggested that lead poisoning is associated with lead-protein complexes. In that study lead was identified by a careful extraction process on many whole kidneys which isolated a quantity of inclusions sufficient for chemical analysis. Our work, in addition to localizing the lead, shows that calcium and phosphorus are co-deposited with the lead in these complexes, a result consistent with the hypothesis of the importance of lead-protein complexes.

Direct-current Potentials in the Human Brain evoked during Timed Cognitive Performance

WALTER *et al.*¹ observed that when a human subject is presented with two sequentially paired stimuli so that the first serves to signal the occurrence of the second, a negative d.c. shift occurs during the interval between the stimuli in an averaged scalp EEG recording; he termed this phenomenon the "contingent negative variation" (CNV). CNV is frequently elicited with fixed foreperiod decision tasks, which may be said to include a "hold" phase, from the warning signal (WS) to the task stimulus (TS), and an "operate" phase, following the TS and terminating with the subject's response (R) to the TS (Fig. 1). CNV definitely occurs during the hold phase, so long as the subject is motivated and the task is sufficiently difficult²⁻⁶, but it has not been demonstrated that CNV is present during the operate phase. The tasks used in previous experiments have been so simple that TS and R occurred virtually simultaneously, and it could not be determined whether the termination of CNV covaries with the TS (the end of the hold phase) or with R (the end of the operate phase). In these experiments CNV was averaged during several complex cognitive tasks with considerably longer operate phases, and found to persist throughout the operate phase, for periods ranging up to 8 s after the TS.

Fig. 1. Two phases of fixed-foreperiod decision tasks. The operate phase may be extended by making rules more complex.

Five male and five female students between 19 and 26 years of age served as subjects. The electroencephalogram and a record of eye movements were recorded from non-polarizable Ag-AgCl electrodes attached to the scalp at the vertex and over the left eye orbit, with a reference electrode on the left ear. These signals were amplified by means of low-level d.c. biological amplifiers set at a gain of 10,000, and averaged on a computer of average transients. In the initial experiment, the WS-TS interval (the hold phase) was set at 1 s. The reaction time of the subject was defined as the time from TS to R (the operate phase); R was recorded from a microswitch which reset a print-out frequency counter. The WS was a 50 ms 900 Hz tone pip, 80 db above absolute threshold. The TS consisted of two digits rear-projected onto a ground-glass screen set at eye level 70 cm in front of the subject, exposed for 100 ms at 27 foot-Lamberts. The digits subtended 4° of visual angle, and a fixation light was centred between them. Trials were presented in blocks of eighty. Inter-trial intervals were randomly ordered, and were 3-6 s long. At the beginning of every session the subjects were given the instructions for the task and then practised until their performance was error-free. Reaction times were examined periodically during practice; when 90 per cent of the responses were within 20 per cent of the mean reaction time, response variance was judged to be sufficiently low for CNV averaging. All CNV averages were computed from an N of 20, with sampling epochs of 2 s. To avoid eye-movement artefacts⁷ those averages were rejected in which more than 10 per cent of the sampled epochs showed any deflection in the eye-movement record. Two different sets of instructions for pressing the response button were used on different trials to manipulate reaction time. The first set, simple reaction time, required the subjects to press on every trial, to every TS. To ensure that they attended to

the digits and not to brightness changes alone, they had also to count the number of times during each session that the TS was changed. In the second set, selective reaction time, subjects were told to press only on certain trials and not on others—for instance, to press only on even numbers, or when the two digits were the same, or when the product of the digits exceeded a given number.

Fig. 2. Averaged contingent negative variations ($N=20$) for one subject showing the relation of corresponding reaction time frequency histograms to the amount of d.c. activity present after the TS (shaded areas). Relative negativity at the vertex is downward. Reference electrode: left earlobe. MRT, mean reaction time in ms.

CNV was elicited from all subjects. The time from TS to the termination of CNV (judged by its return to pre-trial voltage level) was highly correlated with reaction time: the Pearson product-moment correlation across all subjects was 0.81 (d.f. = 17; $P < 0.01$). In Fig. 2 averaged CNV records from one subject on two different sessions are juxtaposed with corresponding reaction time histograms for both simple and selective reaction time. The shaded areas under the curves indicate the amount of negative d.c. activity present between the TS and CNV termination. The amount of negativity is proportional to the reaction time, that is, to the length of the operate phase of the task. There was no significant correlation between CNV amplitude and time of CNV termination across tasks ($r=0.11$; d.f. = 17; $P < 0.10$); this rules out the interpretation that the correlation of CNV duration with reaction time is due to an amplitude-related change in the slope of the return of CNV to pre-trial baseline.

In the second experiment CNV was studied with two longer-lasting cognitive tasks, in which the operate phase could be extended out as far as 10 s. The first was a mental arithmetic problem. The WS-TS interval (the hold phase) was set at 3 s. The WS was a 50 ms 900 Hz tone pip, 80 db above threshold. The TS was a two-digit number spoken by the experimenter into an intercom on a timing signal. The subject was instructed to multiply the TS by a constant given to him before the first trial, and to state the product on hearing the instruction "report" delivered 4 s after the TS. The computations were sufficiently difficult that they required 3-4 s for solution. The operate phase of this task extended from TS to the verbal report, a period of 5-6 s, depending on the latency of the verbal response. The second task was a short-

term memory paradigm. No WS was presented because the longer duration of the stimuli made a foreperiod useless. The TS consisted either of a series of five digits presented acoustically at a rate of one digit per second, or a picture containing an array of conventional objects—houses, trees, animals and so on—projected onto a screen, 150 cm in front of the subject for 4 s. The task instructions were to remember the contents of the TS as accurately as possible, and then to recall them on the instruction "report" 6 s after the TS. The operate phase of this task began with TS offset, extending until the verbal response, a period of about 8 s. The 4 s stimulus exposure period possibly contained elements of both hold and operate functions. As in the reaction time sessions, CNV averages were computed from an N of 20. Sampling epochs were 16 s in duration, in order to include WS, TS, R, and the termination of CNV. Eye-movement artefacts were eliminated in the same manner as in the reaction time sessions.

Fig. 3. Averaged contingent negative variations ($N=20$) for three subjects showing the relation of performance of different cognitive operations to duration of contingent negative variation. Relative negativity at the vertex is downward. Reference electrode: left earlobe. A, Multiplication task; B, digit storage and recall; C, storage and recall of pictorial stimuli.

In the mental arithmetic task a reliable CNV developed during the WS-TS interval (Fig. 3A) similar in amplitude and slope to the negativities previously observed during the "hold" phase. During the TS-R interval, or operate phase, CNV was sustained, peaking an average of 1.25 s after TS. Thus, if anything, the operate phase of the task increased the amplitude of the CNV that had developed in the foreperiod. Although the time of CNV termination varied considerably between subjects, in all subjects it occurred after the onset of the verbal response. In the short-term memory tasks CNV was present during the operate phase of both digit and pictorial recall. It can be seen in Fig. 3B that on the digit recall task, CNV developed during the TS presentation reaching peak amplitude shortly after the final digit in the series, and continuing until the verbal report some 10 s later. On the picture recall task (Fig. 3C) CNV developed briefly after the onset of the TS, lasting for only about 2 s, resuming an average of 1.5 s after the offset of the TS and continuing until verbal report. Two prominent positive waves occurred in the

latter records, time-locked to the onset and offset of the stimulus, possibly related to the on and off responses described by Clynes⁸. The picture recall task did not evoke CNV as reliably as any of the other tasks. CNV, occurred on 56 per cent of the sessions while flat averages, showing no d.c. shifts, were observed in the remaining 44 per cent.

There are three current hypotheses about the functional significance of CNV. The first claims that CNV is the human equivalent of the negative d.c. shifts described in cats by Rowland^{9,10}, and simply another correlate of general behavioural activation. Although compatible with the results of this specific study, this theory is improbable for CNV cannot be elicited in man by one of the most commonly accepted activation paradigms, the orienting response to sensory stimulation, and indeed the human orienting response seems to produce a positive, rather than a negative, deflexion in the averaged EEG (ref. 11). The second hypothesis holds that CNV is a "readiness" potential constituting part of the evoked motor responses which accompany motor movements^{12,13}. This interpretation is weak because CNV has been observed in subjects who are producing no overt motor movements but simply anticipating an interesting stimulus¹⁴. Furthermore, in this study CNV lasted for periods of up to 8,000 ms after the TS, often with a peak 4,000 ms before the command eliciting the motor response; whereas negativities preceding previously described motor potentials last only 300–800 ms, peaking immediately before the overt movement. The third hypothesis suggests that CNV is related to expectancy and attention to stimuli¹⁵; but while these terms apply to the empty-interval hold phase, it is not clear how they apply to the complex operate phases used here. In view of this, it is simpler to forgo these hypotheses and hold that CNV occurs during any period of intense, short-term concentration, and not only during simple anticipatory states, which constitute one of several ways of inducing concentration. Thus the behavioural correlates of CNV may indicate the presence of a functional system distinct from the general arousal system which serves to facilitate concentration on all phases of task performance, perhaps by minimizing distractions or stabilizing central and peripheral posture.

I thank Dr D. Bindra and Dr J. Campbell for support and advice, and Mr G. Tait for assistance. This research was supported by a contract between the US Office of Naval Research and McGill University and a grant from the Defense Research Board of Canada.

Energy Flow and Species Diversity in a Marine Phytoplankton Bloom

MARGALEF¹ has attempted to predict the ways in which certain descriptive (but quantitative) properties of an ecosystem will change during the development of the ecosystem, or when the system is subjected to disturbance. Briefly, the hypothesis he uses states that the transition of an undisturbed ecosystem from a juvenile to a more mature condition is characterized by changes in the system such as the following: an increase in the amount of primary production; an increase in the total biomass; a decrease in the ratio of primary production to biomass; a greater efficiency of production; an increase in the species diversity; a decrease in the ratio of production to respiration; an increase in the importance of stratification and spatial organization. Some of these ideas have been criticized by Slobodkin² as lacking in empirical justification. The results of our field observations on the energy flow in a marine phytoplankton population³ lend support to the views of Margalef and of Odum⁴, but certain weaknesses in the hypothesis are exposed when an attempt is made to apply it to real data.

The observations were made during the spring diatom bloom in St Margaret's Bay, Nova Scotia; all measurements were made at the same station, roughly one mile from the shore, depth 58 m. Six depths were sampled: 1, 5, 10, 15, 25 and 40 m. The station was occupied eleven times between March 28 and April 29, 1969; all phases of the spring maximum were covered. The biomass of plankton was estimated, as particulate carbon, as cell density, and as chlorophyll *a*; relative production was expressed in terms of the quantity $k_b = P(z)/I(z)$ where $P(z)$ is the primary production at depth z measured by the *in situ* ¹⁴C technique and $I(z)$ is the available light at that depth; both P and I are in calories⁵. The ratio of photosynthesis to respiration (P/R) was estimated by the dissolved oxygen technique. Species diversity D was computed from the equation $D = -\sum p_i \log_2 p_i$ where p_i is the probability that an individual belongs to the i^{th} species; the pigment diversity, c/a , was measured as the ratio of chlorophyll *c* to chlorophyll *a*. The age of the bloom was assessed by taking the arbitrary zero of time on the first sampling day.

The partial correlation matrix for the results is shown in Table 1. The ratio of chlorophyll *c* to chlorophyll *a* was well correlated with species diversity. In this respect the c/a ratio is analogous to the pigment index (that is, the ratio of optical densities at 430 nm and 665 nm of acetone extract of plankton) of Margalef, which has been found to be a good predictor of species diversity. Both species diversity and c/a had significant negative correlation coefficients with the age of the bloom. Neither species diversity nor c/a was significantly correlated with the concentration of either phosphate or nitrate, but in every case the sign of the correlation coefficient was as expected (negative). Low values of species diversity were associated with high values of P/R ratio. There was a significant trend of decreasing P/R with age of the bloom. The relative productive efficiency k_b increased with depth. There was a strong negative correlation between k_b and species diversity.

These results are entirely consistent with current ideas of ecosystem dynamics as set out by Margalef and Odum. One might also have anticipated significant correlations between species diversity and depth, P/R and nutrients, and k_b and age, none of which materialized.

At first sight, however, the highly significant negative correlations between species diversity and all measures of the standing stock of phytoplankton seem to run counter to Margalef's general thesis that increases in biomass are associated with increases in diversity. But we feel that the contradiction might be resolved by drawing a distinction between short term and long term responses of the system. In our opinion, the confusion of many different time scales constitutes an important weakness in present ecological theory. If these concepts are to be made operational—and they must if they are to be relevant—then some basis must be found to disentangle the confounding of processes with widely divergent time constants. We must know whether we are to apply the same principles to systems with a lifetime of the order of days as to systems more appropriately considered on the geological time scale. This point has been made previously by Deevey⁶.

Table 2. PARTIAL CORRELATION COEFFICIENTS BETWEEN VARIOUS MEASURES OF P/B AND SOME OBSERVED QUANTITIES

Each coefficient is based on 34 degrees of freedom

† Exceeds value expected at 5 per cent probability level, but less than 1 per cent.

Margalef considers the ratio P/B (primary production to total biomass) to be an important parameter in ecosystem theory. In our data the ratios of k_b to any of the measures of standing stock give estimates of P/B . The quantity of carbon should be the best measure of total (that is, both living and dead) biomass, for in counting cell numbers one normally excludes "dead" cells, and chlorophyll *a* can be measured free from its degradation products. The ratio k_b/carbon , therefore, is closest to the intent of the parameter P/B . It is interesting then, that k_b/carbon was the only measure of P/B which had a significant partial correlation with species diversity (Table 2). This not only supports the principle that increasing species diversity is associated with a decrease in P/B , but also bears out the contention of both Margalef and Odum that non-living biomass may be as important as living material for the organization of the ecosystem. This observation is not without relevance to the controversial status of "organic detritus" in the sea.

The following argument could, however, be made: for some ecosystems, such as forests, where all parts of the cycling system are readily accessible to study, B should include both living and non-living biomass. But in studies of ecosystems such as the plankton ecosystem where an important part of the materials cycle (the benthos) is ignored, B should more properly be a measure of productive potential. In this case P/B would be expressed in terms of $k_b/\text{chlorophyll } a$. This ratio gave the

Residual	34	0.001	

Dependent variable is k_b . Quantity R is the multiple correlation coefficient. ΔR^2 is the increase in the amount of the variance of k_b which is explained by including a particular variable in the regression. The standard error of the estimate is 0.0065.

best correlation with inorganic nutrients, but no correlation with species diversity (Table 2). The difference between this and the previous interpretation is in the amount of emphasis placed on the system itself compared with the importance attached to the organisms and their interactions.

If the only object had been to establish a predictive equation for primary production, it seems that much less work could have been done at the sacrifice of only a little information. Table 3 summarizes the stepwise regression calculation. The square of the multiple correlation coefficient is the fraction of the variance in k_b explained by the regression. Concentration of chlorophyll a could account for 64 per cent of the variation in k_b . Depth accounted for a further 9 per cent of the variance, cell number 7 per cent and nutrients 4 per cent. The other six quantities measured accounted for only a further 2 per cent of the variation in k_b . This is not to deny the importance of these six quantities; the point is that they made little further refinement to prediction of k_b , once changes in chlorophyll, depth, cell number and nutrients had been taken into account. This supports the argument of Platt⁵ that changes in the chlorophyll content of algal cells in response to nutrients, temperature and other environmental factors enhance rather than detract from the value of chlorophyll as a standing stock index in the prediction of primary production.

We have thus found some empirical justification, in natural conditions, for Margalef's hypothesis of ecosystem dynamics. The chief difficulty we find in trying to apply the ideas to real situations is a lack of clarity concerning the various time scales involved; for example, values of P/B could be quite different, depending on the times over which P and B are averaged. The main weaknesses we find in our own treatment are, first, that the inadequacies of the linear model may have obscured some important information and, second, that we have ignored Margalef's timely hint of the importance that derivatives (in the sense with which the word is used in calculus) must play in the future progress of ecological understanding.

We thank Dr L. M. Dickie, Dr I. A. McLaren and Dr K. H. Mann for constructive criticism of the manuscript.

Distribution Pattern of the Duplication of Discoveries

PRICE¹ conjectured that a Poisson distribution might be a good fit for the pattern of incidence of multiple discoveries. We have fitted a modified Poisson distribution to the frequency of duplication of discovery of antibiotics.

We have considered the discovery of an antibiotic to have been duplication if it was identified with another antibiotic and so reported in published documents, irrespective of whether the compounds were produced by one and the same or different species of microorganisms². We used the data reported earlier³ on the frequency and duplication of discovery of antibiotics during 1907-1966 after correcting a few minor discrepancies. As there was practically no duplication of discovery of antibiotics from bacteria, we have dealt only with the pattern relating to two groups: (1) fungi, algae and lichens, and (2) actinomycetales.

A normal Poisson distribution did not fit the distribution pattern of duplications, but a modified version³ did. For such a distribution, the p.d.f. is

$$\left(\frac{c}{c+1}\right)^p \frac{p(p+1)(p+2)\dots(p+(r-1))!}{(r-1)!(r+1)^r} \quad (1)$$

where p and c are constants to be estimated using the following relations

$$\text{mean of } X = p/c \quad (2)$$

$$\text{var } (X) = p/c + p/c^2 \quad (3)$$

Using equations (2) and (3), p and c were estimated separately from the data on antibiotics derived from the two groups of organisms and for the pooled data. Using formula (1), the expected frequencies were computed. A χ^2 test was done. To fit the distribution, the upper tail of the distribution from duplication frequency 8 and above was omitted. Table 1 gives details of the goodness of fit. In all three cases, the goodness of fit was confirmed.

Table 1. OBSERVED AND EXPECTED FREQUENCIES OF DUPLICATION, AND TEST OF GOODNESS OF FIT

No. of times duplicated	No. of antibiotics from fungi, algae and lichens		No. of antibiotics from Actinomycetales		Total	
	Observed	Expected*	Observed	Expected*	Observed	Expected
0	371	364.2	1,018	1,011.6	1,380	1,380.5
1	39	44.3	79	81.9	118	121.5
2	12	15.8	20	20.5	32	44.2
3	7	6.9	15	13.3	22	20.2
4	2†	3.3	7	6.7	9	10.1
5	4†	1.6	7†	3.5	11	5.4
6	2†	0.8	4†	1.9	6†	2.9
7	1†	0.4	1†	1.1	2†	1.7
	2.98		8.23		12.25	
χ^2_{cal}	9.49 for 4 df		12.59 for 4 df		12.59 for 6 df	

* Value corrected to first decimal place.

† Grouped data used.

There thus seems to be predictable regularity in duplications, and Price's conjecture about the pattern of distribution of multiple discoveries is confirmed for antibiotics, even in cases where there are no duplications.

HISTORY OF BIOCHEMISTRY

The Chemistry of Life

Eight Lectures on the History of Biochemistry. Edited by Joseph Needham. Pp. xxx+214. (Cambridge University: London, April 1970.) 60s; \$9.50.

HISTORICAL aspects of science nowadays tend to occupy little time in the education of scientists. Students are liable to argue that there is so much to be learned about the present state of their subject that they cannot spare time for the study of the history. The truth is that some time spent on historical aspects is by no means wasted because a full understanding of scientific knowledge and of the nature of research requires a study of the historical development of the subject. In the introduction to this book the editor mentions that Frederick Gowland Hopkins, the "father" of British biochemistry, never lost an opportunity of referring to events of historical interest. "Whether it was van Helmont capturing the 'wild-gas' in breweries, or Captain Lind protecting his men from scurvy with citrus fruits, or Berzelius finding lactic acid in the muscles of hunted stags in 1808, or Fick and Wislicenus romantically climbing the Faulhorn to settle the relation of protein metabolism to muscular work—all were brought in to give colour and perspective, to enlarge our understanding of our past."

This book is the outcome of a course of lectures given by Cambridge biochemists some ten years ago. Joseph Needham, in his introduction, deals with the forerunners of biochemistry beginning with the Greek pre-Socratic philosophers of the sixth and fifth centuries BC, early Indian and, of course, Chinese achievements through the middle ages until the eighteenth century. His valuable list of references leads those interested to the sources. Robert Hill describes the growth of our knowledge of photosynthesis and Malcolm Dixon discusses the history of enzymes generally and of biological oxidations in particular. E. F. Gale covers the development of microbiology from the days of Leeuwenhoek to the twentieth century, discussing the argument on spontaneous generation, the nature of fermentation and the germ theory of disease. A long and highly original section, occupying almost one third of the book, written by Kendal Dixon, is headed "Some Biochemical Signposts in the Progress of Neurology". The concepts of Vesalius, Descartes, Willis and Albrecht von Haller on the function of the brain, as well as the eighteenth and nineteenth century ideas and experiments, are discussed and documented by detailed quotations. F. G. Young deals with the evolution of the concept of animal hormones and Leslie Harris with the discovery of vitamins. Mikuláš Teich traces the foundations of modern biochemistry, beginning with Lavoisier. The final chapter, by Sir Rudolph Peters, entitled "Some Lone Pioneers of Biochemistry in the 19th Century", selects for treatment Wollaston (who discovered uric acid in the chalky deposits of gout, and cystine in a kidney stone), Andrew Buchanan (who did important work on blood coagulation), Bence-Jones (whose name is still well known as the discoverer of a special urinary protein), Alfred Garrod (an expert on gout)

and his son Archibald Garrod (the originator of the concept of inborn errors of metabolism).

Reading this book brings home the difficulties which future historians may face when they attempt to write accounts of the more recent events in science. The rapid growth and the ever increasing complexity of science makes the task of the historian a very formidable one. So I think that it is becoming increasingly important that those who have personally participated in the progress of science, or witnessed it from close quarters, should be encouraged to write histories of their own special field (as Keilin did in his *History of Cell Respiration and Cytochrome*). Others are unlikely to master adequately the intimate details. As Watson's *Double Helix* forcefully illustrates, the published papers often omit historically interesting and relevant aspects of scientific developments. Already long ago Ampère was blamed that "having built up a perfect demonstration he removed all the traces of the scaffolding by which he had raised it". In these days of team work, and of frequent personal contacts between scientists, ideas tend to mature informally and the published accounts report too little of the maturing process. It is therefore welcome news that there are now historians of science who concern themselves with very recent history and try to supplement information contained in ordinary research papers by personal interviews with the scientists who have made history.

H. A. KREBS

HOME CURES

American Indian Medicine

By Virgil J. Vogel. Pp. xx+583. (University of Oklahoma: Norman, February 1970. Distributed in the UK by Bailey Bros. and Swinfen.) 118s; \$12.50.

THE title of the book might suggest that the author was a medical specialist or at least a physical anthropologist, and it is a pleasant surprise to find that he is, in fact, a Chicago historian. Dr Vogel, by this important reference work, demonstrates clearly that historians can contribute no less positively to medical anthropology.

The principal subject matter of the book is concerned with the influence of American Indian medical practices on European settlers. As the preface points out, the majority of studies on Amerindian medicine concentrate on the ritual aspects and tend to neglect the extensive use of more rational therapy. In particular, the Amerindian has investigated and selected for use a surprisingly large number of indigenous plants.

The case for the influence of Amerindian herbs and drugs in the western world was in some quarters resisted, perhaps because substances such as decomposed corpse and menstrual blood were also part of their materia medica. But the sixteenth century European pharmacist was no better, with his mummy dust, pigeon excrement and stag's penis. The fact is that, as regards Amerindian plant lore, we have a very interesting example of counter-acculturation, with the so-called dominant progressive group receiving varied information of lasting use and value (cocaine, cochineal, cinchona, curare, ipecac, vanilla, guaiacum, chenopodium, balsams and so on). But Vogel is not trying to argue that the American Indians generally used scientific methods of experiment and reasoning in adopting remedies and methods of treatment, although the treatment of fractures, dislocations, wounds and bites were usually rational and often effective. He simply wishes to provide detailed evidence to show that combined with the superstitions and untested beliefs which were so much a part of their medicine, there was also a hard-core of procedures and discoveries which have influenced, or at least put into better perspective, the development of medicine in the western world. For instance, it is clearly wrong to give the British credit for a cure for scurvy, when it is known that the Indians

successfully treated Jacques Cartier's men for the disease on the St Lawrence River as early as 1535. Even the shamanistic practices are clearly worth considering, as Vogel has done, for more than their ritualistic relevance. As Professor Ackerknecht pointed out some years ago, these apparently useless rites may in actual fact have been of considerable psychotherapeutic value, and should not be underrated in this respect.

In terms of overall content, the first third of the book considers Indian theories of disease and shamanistic practices, a regional survey of the early observations on Indian medicine made by European settlers, and of the influence of such medicine in the early colonies. Following this is a short but useful account of the historical evidence for Amerindian health during the earlier period of European contact. The chapter on Indian therapeutic methods is long and detailed, and together with the accompanying appendix on American contributions to pharmacology, this latter part of the book will remain an important reference source for many years. The bibliography of forty-four pages is thorough and up to date.

DON BROTHWELL

IN SEARCH OF A ROLE

Training Tomorrow's Psychiatrist

The Crisis in Curriculum. Edited by Theodore Lidz and Marshall Edelson. Pp. xiv + 94. (Yale University: New Haven and London, June 1970.) 18s paper; 60s boards.

DURING the ten years since the Mental Health Act (1959) became law, there has been a constant pressure for change in the practice of psychiatry, not only in Britain but throughout the western world. The pressure comes partly from within the profession itself: in many European countries, psychiatry has been dominated, to its detriment, by the vested interests of neurologists. In turn, Holland, France and West Germany have taken steps to separate these two related and yet profoundly different disciplines. In Britain, the Royal Medico-Psychological Association has been in labour for the past six years trying to give birth to a Royal College of Psychiatrists. In America, the 1963 "Community Mental Health Centers Act" has opened up new professional careers, challenging the dominance of private-practice individual psychotherapy.

To an even greater extent, however, the pressure for change has come from the public, in the form of increased readiness to seek psychiatric help, and raised expectations of the help which should be available to relieve emotional distress. Public demands and political initiatives have accelerated changes in the patterns of mental health care on both sides of the Atlantic. In Britain, the recommendations of the Todd Commission, which advocated that more attention be given to the behavioural sciences, to psychiatry and to community medicine in the future training of doctors, have nowhere yet been implemented; but significantly, the Seeborn Report on the Personal Social Services, published shortly after Todd, has already transformed and greatly extended the role of the social work profession. (In a little-regarded paragraph, the Seeborn Committee drew attention to the apparent confusion among psychiatrists as to their proper role in dealing with the enormous problem of minor mental ill-health among children and adults.) In the United States, the very multiplicity of experiments in trying out new methods of providing mental health care has added to the confusion: psychiatrists, psychologists, social workers and non-professional community leaders have all severally claimed the right to direct and control community mental health programmes.

It was against this background of tumult and confusion that a group of psychiatrists met recently at Yale to discuss the future training of psychiatrists. Four of their papers are presented in this booklet, together with

a foreword by Dr Theodore Lidz. The two opening papers stress the need for psychiatrists to have medical training, but suggest that the biological side of that training can be attenuated in favour of early specialization in psychiatry proper. The third paper outlines an ambitious and clearly intellectually demanding undergraduate elective course in behavioural science for future psychiatrists, while the fourth examines the conflicting views about what constitutes "community psychiatry", and presents some guarded opinions about how psychiatrists should be trained for this still ill-defined field of action.

Dr Lidz's preface ends with the following sentences: "The papers included in this volume do not provide solutions nor do they cover all of the significant problems confronting psychiatric educators. They consider some of the significant issues and raise many questions. In a sense, the meeting at which they were given explored the need for new directions in educating psychiatrists, and indicated the need for a conference at which the issues could be examined more fully and definitively". These sentiments, echoing the aside in the Seeborn Report, are no less true of British than of American psychiatry today.

G. M. CARSTAIRS

SLAVE SYNTHESIS

The Atlantic Slave Trade

A Census. By Philip D. Curtin. Pp. xix + 338. (University of Wisconsin: Madison and London, May 1970.) 71s; \$7.50.

IN the preface to this book, the author stresses that it is neither a textbook nor a definitive monograph. In common with most other academics Africanists have contributed, during the past quarter of a century, an increasing number of works at both ends of the publishing spectrum. Young scholars have been more or less forced to undertake their first major investigation in the field and on relatively narrow topics and, in consequence, the library thesis (or synthesis) has become less and less acceptable. Experienced scholars have been tempted by publishers to write the broad works of synthesis for which there would seem to be an ever increasing demand. Conversely, book-length syntheses of fairly large topics at an intermediate level have been relatively rare. The Atlantic slave trade was just such a topic and no real attempt had been made to review the considerable secondary literature on it, most of which had been published since 1945. In attempting to do so, Professor Curtin conceived his task as "building with the bricks that exist, not in making new ones". Where there is a consensus among authorities he has let it stand; where no consensus exists, he has looked further but stopped short of original research.

As the subtitle indicates, this book is a census. Its aim is to appraise and collate information on the African origins and New World destinations of the slaves, the numbers involved in the transatlantic trade and the fluctuations therein through almost four centuries. It reflects a recent trend towards quantification in historical scholarship. There are several semi-logarithmic graphs, eighty-three tables and an acknowledgement in the preface to the assistance of the University of Wisconsin's Computing Center. While the author stresses that the estimates may be in error by as much as twenty per cent, he nevertheless demonstrates their value in measuring the relative importance of different geographical branches of the trade at different times. For example, less than a twentieth of all the slaves were imported into British North America, whereas more than a third went to Brazil. Contrasts were almost as marked through time, so that possible large errors do not seriously mask the trends.

The book is well presented, contains numerous simple but effective maps, and is well indexed. It can be read or

referred to with equal facility. Apart from a final interesting chapter on mortality it sticks closely to the stated theme and adheres to its self imposed rules.

One hopes that in the nineteen-seventies more scholars in more fields will publish book-length syntheses of this type. If it does not happen, then even the best and most significant findings of original scholarship will fail to get into the textbooks. The gap between research and teaching will then have grown too wide to be bridged.

G. MALCOLM LEWIS

ONE MAN'S CONTRIBUTION

The Transmission of Passive Immunity from Mother to Young

By F. W. Rogers Brambell. (North-Holland Research Monographs—Frontiers of Biology, Vol. 18.) Pp. xvi+385. (North-Holland: Amsterdam and London, 1970.) Hfl. 65; 152s; \$18.20.

WITH the death of Professor Brambell developmental biology has lost one of its finest and most respected mentors. The publication of this volume at such a sad time was coincidental but perhaps appropriate. In it, his most important contribution to our knowledge of the acquisition of humoral immunity by the foetus and newborn is extensively described with characteristic thoroughness and lucidity. Published as one in a series of excellent monographs it presents a systematic examination of both prenatal and postnatal transmission of maternal antibodies to the young in a variety of species.

The writing of a monograph has unfortunately become one more hurdle in a scientist's career, something that one is expected to do. As a result the average reader is bombarded by expensive prestige books often of the very lowest intellectual quality, shrapnel in the information explosion. Professor Brambell's book is most certainly not one of them. It is simply an excellent review and summary of one man's contribution to his subject. The quality of the book lies in the very high standard of experimentation presented, in the clear exposition of theory, and in the intellect of the author.

For each species there is a detailed account of placentation and the structure of the foetal membranes, followed by an elegant analysis of the mode of transfer of antibodies both before and after birth. The species examined include birds, marsupials, rodents, the cat, the dog, the hedgehog, ruminants, the pig and, finally, monkeys and man. One splendid chapter considers the association between the transmission of antibodies and haemolytic disease of the newborn in many species and ends with an intriguing paradox; the absence of haemolytic disease in newborn ruminants. Experimental immunization studies show the development of the appropriate antibodies and their subsequent transmission to the young through the colostrum. Such antibodies are haemolytic *in vitro* and yet the young are unaffected.

The final section is an erudite collection of conclusions and hypotheses. With its emphasis on the selective transmission of antibody and the probable presence of specific globulin receptor sites on cells it clearly outlines the resemblances between antibody transmission and anaphylactic sensitization. How can a complex protein like antibody globulin survive its passage through a cell packed with proteolytic enzymes? Professor Brambell argues with conviction that specific receptors bind to the globulin and inhibit enzyme digestion within the phagosomes. Saturation of these receptors causes excess globulins to be degraded; a simple yet elegant theory amply supported by experimental evidence. Indeed, most statements made in this book are backed by abundant evidence. Forty-two pages of references may seem excessive in some books. In this one they are an integral and vital part.

The price of this volume will no doubt limit it to the

shelves of institute libraries and a few well-heeled developmental immunologists. It is no doubt a book for the specialist in spite of its obvious relevance to practical clinical problems. To one reviewer at least it is a source of delight and an excellent reminder of the qualities of the late Professor Brambell.

G. A. CURRIE

LIVELY EMBRYOLOGY

Cells Into Organs

The Forces that shape the Embryo. By J. P. Trinkaus. (Foundations of Developmental Biology Series.) Pp. xvi+237. (Prentice-Hall: New Jersey and Hemel Hempstead, 1969.) n.p.

EARLY students of cell behaviour in morphogenesis were, of course, well aware of the possible roles of change in cell size and cell shape. But they undervalued cell movements and were often over impressed by the importance of differential activity. We owe to Wilson, Vogt, Pasteels and Holtfreter the first development of a fresh approach the outcome of which is very well surveyed in Dr Trinkaus's book. It is noteworthy that he hardly has occasion to mention cell division and that when he does it is without exaggerated respect. Nevertheless, it is fair to suspect that it will return to a qualified favour in the future—not as solely responsible for any morphogenetic change, but as an important participant in some.

At the present time the parameters of cell behaviour most intensively studied are the strength and specificity of inter-cell adhesions, the modes of cell motility, and the social behaviour of cells the properties of which may depend critically on the company they keep. In each case the part of the cell most immediately involved is its surface. In each case a combination of *in vivo* and *in vitro* work on living cells must be supplemented by fine structural study and chemical analysis. Already some seemingly complex pieces of morphogenetic activity promise to yield to analysis in fairly simple terms.

Trinkaus provides a good, and much needed, account of this lively field. It will serve equally as a primer of cell biology for embryologists and of morphogenesis for cell biologists. He draws on a very wide range of material and is helpful in making clear the nature of contemporary disagreements. He is, however, more than clear; he succeeds in conveying real enthusiasm for the problems he describes.

D. R. NEWTH

PICTORIAL ULTRASTRUCTURE

Cells and Tissues by Light and Electron Microscopy

Vol. 1: Microscopie Photonique et Electronique de Tissus et de Cellules. English version by Edmund B. Sandborn, French by R. Gagnon, P. Jean and B. Messier. Pp. xiii+366. (Academic: New York and London, March 1970.) 135s.

ATLASES of ultrastructure are now commonplace and any new contribution has to offer something special to compete. This work is larger than most; it is, in fact, the first of two volumes and deals with the cell and basic tissues such as epithelia, muscle, nerve, connective tissue and lymphoid organs. Volume two will cover other systems such as endocrines, circulation, digestion, excretion, and the like. The special feature one is led to expect from the publisher's leaflets and from the dust cover is a thorough correlation of light and electron microscopy. It is claimed that the book "is a coordinated study of animal cells and tissues as seen in the light and electron microscope. . . . It is the first attempt at providing a study of biological structure which includes both light and electron microscopy". From this one might expect a careful comparison between the histology and histochemistry of a tissue and its ultrastructure. This is something that is lacking in the literature and it would be extremely valuable. This

book makes no attempt to cover the gap. To begin with, fewer than one in seven of the photographs is taken at light level; even these are not of ordinary histological sections but chiefly of toluidine blue-stained 1 μ Epon sections. Histochemistry is almost unrepresented. One can only describe the dust cover and title as grossly misleading.

The preparation methods are slightly different from those in general use. Tissues were fixed in 6.25 per cent glutaraldehyde and 2 per cent acrolein in phosphate buffer and postfixed in 2 per cent osmium tetroxide. The first solution seems rather concentrated. It is difficult to say whether this or some other factor is responsible for the very dark and grainy appearance of many of the photographs. The quality of the latter varies. A few are excellent, most are only average and a fair number are distinctly poor. The text is generally helpful but sometimes excessively brief. The wisdom of printing the text in both English and French is doubtful. It must have added to the cost. A more extended text in one language would have been preferable in places.

On the whole this is a disappointing first volume; it does not live up to the claims made for it.

R. BARER

BIOCHEMISTRY OF ANDROGENS

The Androgens of the Testis

By Kristen B. Eik-Nes. Pp. xi + 249. (Dekker: New York, March 1970.) \$14.75; 140s.

THIS monograph discusses the quantitation of testosterone and androstenedione, and attempts to summarize present knowledge of how the vertebrate testicular androgens are formed in the male gonad. It gives the mechanisms responsible for the formation of these androgens and a good chapter on how they are broken down in the body.

The book commences with a chapter on the "Synthesis and secretion of Androstenedione and Testosterone" by Professor K. B. Eik-Nes which gives an excellent picture of the steroid enzymes involved in the synthesis of androstenedione and testosterone.

The section on the formation of oestrogens by the male gonad is interesting. There is no doubt that there may be species differences here, and there seems to be good evidence today that secretion of oestrogens in man by the testes is really insignificant and they may not be secreted at all, being totally produced by peripheral conversion of androstenedione. The next chapter on the "Catabolism of Testosterone and Androstenedione" describes fully the principal catabolic sequence and the end products of catabolism, and discusses the regulation of androgen catabolism and catabolic hormone activity. This is followed by a chapter on gonadotrophic regulation of testicular function. The comment made here, that the intact gonadotrophic responsive cell may not be permitted to express its full steroidogenic capacity without gonadotrophic stimulation, and that it was as if the cell was normally damped down and the trophic hormone released the cell from some inhibitory influence, is certainly very interesting. The book ends with a chapter on the "Estimation of Androstenedione and Testosterone by Physicochemical Methods" by Dr H. J. van der Molen. This chapter is well prepared, but unfortunately is far too bulky in the context of the subject matter of this monograph. Every type of method used to measure the androgens is critically reviewed. Unfortunately, one cannot entirely agree with the author's table of merit for the various methods used for measuring androgens—there seems to be a bias towards competitive protein binding techniques. While these techniques may undoubtedly be our best approach today until we produce reasonable specific antisera to testosterone and androstenedione and then perform solid phase radio-immunoassays, the figure

of 2 for saturation analysis against the figure of 6 for electron capture gas chromatography as precision merit figures, is hardly justified. Again, competitive protein binding techniques for testosterone using sex binding globulin have not been entirely satisfactory in many laboratories, and problems have occurred with high blanks.

In spite of a certain appeal of this book, because it brings together a lot of information about testosterone and androstenedione, it fails to portray the fascinating story of vertebrate testicular androgens. While some of these more interesting aspects are to be found in the book, they are only very briefly touched on. A small section discusses the secretion of androgens throughout life, but only cursory mention is made of the critical events of Mullerian and Wolffian duct fusion, and there is no mention at all about the effect of testicular androgens of the sexual differentiation of the brain. Again, one feels more ought to be written about the hormonal control of spermatogenesis, and the hormonal control of the epididymis, because surely the major purpose of the secretion of testicular androgens is to preserve and control spermatogenesis, the chief function of the testes. The possible physiological significance of di-hydrotestosterone and its possible role as an active form of testosterone in some androgen-sensitive organs is again treated very lightly.

Nevertheless, the chief concern of the book is the biochemistry of androgens, so it should be of interest to graduate students working in endocrinology of the testis and to post-doctoral fellows interested in reproductive endocrinology and steroid biochemistry. Unfortunately, besides its faults it is rather expensive for its 250 pages.

DONALD EXLEY

INSECT TAXONOMIST'S GUIDE

Taxonomist's Glossary of Genitalia in Insects

Edited by S. L. Tuxen. Second enlarged edition. Pp. 359. (Munksgaard: Copenhagen, 1970.) 200 D kr.

THE publication of the first edition of this book in 1956 was something of a landmark in taxonomy because, for the first time, taxonomists had a convenient reference book to the numerous terms applied to the genital structures of insects. The second edition is much enlarged, consisting of 359 pages against the original 284, and all the chapters have either been revised by the original author or revised or re-written by new authors, all of whom are recognized authorities. The original plan of the book remains the same, the principal part consisting of two sections, the first being the description of the genitalia of both sexes of representatives of the various orders, while the second consists of a glossary.

The present work does not aim to attempt the impossible and to try to establish a common nomenclature, although a useful feature in the glossary is that terms applied to homologous structures are indicated. The value of the work lies in enabling a taxonomist to follow descriptions of the genitalia of insects whether he be a specialist or a general taxonomist; it will also be useful to comparative morphologists as a ready reference to some of the range of genital structures.

The 248 text figures, by the authors of the various chapters, are necessarily individualistic, but all are excellent and well labelled. After the description of the male and of the female genitalia of representatives of the particular order, the legends for the figures are given, followed by short references. The abbreviations are explained in one of the initial pages of the book, but additional abbreviations are given for the Hymenoptera.

As with the nomenclature of wing venation, specialists in various orders have tended to apply different terms to homologous structures of the genitalia, while comparative morphologists have attempted to apply terms thought to be indicative of the origin of the structures. Together

with the complexity of most insect genitalia this has resulted in an unnecessary proliferation of names; the most valuable service this work may well achieve is to discourage further coining of terms, and, even better, to reduce the present number. The book is essential to all working taxonomists.

A. BRINDLE

BABOON ANATOMY

Primates

Comparative Anatomy and Taxonomy. Vol. 8: Cynopithecinae. By W. C. Osman Hill. Pp. xix + 680 + 36 plates. (Edinburgh University: Edinburgh, April 1970.) 340s.

I HAVE had the pleasurable task of reviewing the previous volumes in this formidable series and was therefore alarmed to find the number 8 embossed on the latest volume. Whatever happened to volume seven? The first few lines of the preface explains all: volume seven which deals with the macaques and mangabeys is scheduled for 1971; volume eight, bearing the somewhat unfamiliar subtitle "Cynopithecinae" is, for reasons of expediency, out of line. This seems a good decision, bearing in mind the present great interest in the African ground-dwelling Cercopithecinae. Volume eight embraces the genera *Papio*, *Mandrillus* and *Theropithecus* and their extinct ancestors.

We have become so conditioned to the invariability of Dr Osman Hill's scholarship that, with each new volume, it is necessary to remind ourselves of the immense knowledge that has gone into its preparation. Once again, volume eight is an impeccably accurate accumulation of the facts of morphology and taxonomy, but one might wish that behaviour was equally well represented. Possibly this is akin to wishing that Darwin had possessed Mendel's and De Vries' knowledge of the hereditary units. Each generation of scientists contributes to the sum total of knowledge in terms of his own particular expertise. Osman Hill is one of the last of a long line of distinguished primate morphologists and his like, as the saying is, may not be seen again.

Sometimes progress in science is more of a threat than a promise. While scientific progress has its undeniable advantages for mankind, it also has a most depressing effect on the tried and true methods of the basic sciences. If it were true that what is new is necessarily good and what is old-hat is (to use a phrase popular among scientific administrators) unfundable, then the scientists would have no complaint, but is it true? When the electron microscope was introduced, a research project with the light microscope became a non-event, so much so that no ambitious graduate student would willingly opt for the latter if he could possibly climb on the bandwagon of the former. How much information is being missed at cellular level while the eyes of the scientific world are scanning the sub-molecular structure of the cell membrane and its processes? It would be serious indeed if research in primate morphology and the functional interpretation of its discoveries were shunted into the "unfundable" category by the preferentials of new, and as yet unproven, methodologies.

Hill's latest volume will inevitably reach a larger audience than his previous volumes because it deals principally with the baboons which enjoy (if that is the word) a high degree of popularity in the medical research field. For this reason it is perhaps unfortunate that Hill's classification is not wholly in line with recent trends in primate systematics, which is to synonymize the species of *Papio*. It is now recognized that *Papio* is a single polytypic species with morphologically different subspecies interbreeding wherever they meet. Modern taxonomic thought is divided between retaining two species—*P. hamadryas* and *P. cynocephalus*—or treating

them as conspecific; in which case the specific name would have to be *P. hamadryas* under the Priority Rule. Common sense, for the time being, is in the ascendancy and confusion among the ranks of non-taxonomists is postponed by admitting two species—the sacred baboon (*P. hamadryas*) and the common baboon (*P. cynocephalus*). Recent classifications also favour the inclusion of the drills and mandrills in the genus *Papio*, on grounds that are almost wholly pragmatic, and, in my opinion, biologically invalid. Fortunately, the informational content of volume eight of *Primates* is in no way affected by these nomenclatorial niceties.

The book is profusely illustrated with line drawings and black and white plates. It would be nice to see a few more colour plates; the Devil (or in this case the popular monthly glossies) always seems to have the best tunes. What a pity it is that colour is not as readily available to scientists, who often require it to prove their point, as it is to purveyors of sex magazines whose point is already proved.

Anybody who possesses the first six volumes of this series will need no urging to add volume eight to their collection. But for those who have not yet invested in *Primates* and have a special interest in the African Cercopithecinae, this new volume will provide a permanent, accurate, up to date source of historical, morphological and physiological information collected by the acknowledged expert in the field of primate morphology.

JOHN NAPIER

GUIDE TO BRITISH LICHENS

Introduction to British Lichens

By U. K. Duncan, assisted by P. W. James. Pp. lxxiv + 292 + 128. (Buncle: Arbroath, 1970.) 70s.

THE principal object of this book is to assist students and beginners to identify lichens. It does not attempt to be a definitive lichen flora of Britain, and, indeed, it only includes 65 per cent of the species recorded for this country (the other 35 per cent being lichens which the beginner is very unlikely to encounter).

There is no doubt that the book will succeed admirably in its object. It will be extremely useful in lichen identification because the keys are particularly good and are easier to follow than in any other relevant lichen flora; there are adequate descriptions of each species. Unfamiliar terms are explained both in a glossary and in a detailed account of lichen structure in which technical words are put into bold type. There are also lists of species found in different habitats—which, again, will be of great assistance.

The chief defect is the illustrations, consisting of 128 pages of line drawings (unfortunately called plates) which are often tiny, many occupying less than half the space available to them on the page. If all but a few of the illustrations had not been published, the usefulness of the book would not have suffered, and its price would have been brought more comfortably down into the range acceptable to students. Another irritating feature is that in the excellent key to genera, there is no indication of the page on which the description of a genus occurs. Unless the reader has an accurate and very detailed grasp of lichen classification, he will have to continually turn to the index to locate the relevant page.

Perhaps the basic problem is that the book is published by a firm which seems not to have much experience in publishing this kind of scientific book. This is a great pity because the book is essentially very useful. Miss Duncan has a remarkably good and critical knowledge of lichens, and, as those who attend British Lichen Society excursions will testify, she is outstandingly good at helping beginners. All students of British lichens should have this book.

D. C. SMITH

FOR GRASS-SPOTTING SWAGMEN

The Grasses of Central Australia

By M. Lazarides. Pp. xi+282. (Australian National University: Canberra, March 1970.) \$10.0.

MR LAZARIDES provides a valuable catalogue of the grass resources of the arid area of central Australia. Designed for use primarily by non-specialist taxonomists, his book comprises a concise, lucid account of the land and vegetation types in the area, followed by an extensive treatment of the grasses.

Grasses make up most of the forage, and must be adequately known before improved management policies can be effected. In an area so inimical to plant growth, efficient exploitation, or conservation, of the grass flora is urgent, and rests on better knowledge of the taxonomy and ecology of constituent species. Lazarides offers a sound guide to both, and his work must be a spur to further research. Though conditions here are so inhospitable, it is galling for a British grass-spotter to note that the grass flora is richer than that of Britain. Many species show fascinating feromorphic adaptations.

The taxonomic treatment of the grasses is preceded by a short, illustrated account of the morphology of the grass plant. The attempt made to simplify this complex subject, without any bending of the facts, is well done. There is a clear generic key.

Descriptions of species occupy most of the book. Each consists of a general account of habit, with notes on occurrence, distribution and forage value, followed by a detailed "botanic description" of the reproductive morphology. There are good photographs of almost all species, often showing spikelet details. Accounts are rendered less awesome, perhaps, to the non-taxonomist, by relegation of nomenclatural details and citations to an appendix.

Minor criticisms which can be levelled at this book arise from the author's praiseworthy attempt to write for a wide audience. There is much to be said for his alphabetical arrangement of genera and species, but could not one page be spared for listing genera into tribes? The first item in the species descriptions is the common name, followed by the Latin binomial. This may make for readier reference by pastoralists, but the author confesses that to achieve this he invented many common names. Regrettably, these are not identified for the sake of later folk studies. They are merely English names which may become common only through the relentless action of natural selection. Brawny cattlemen, perceiving *Eragrostis* from their galloping steeds, may scorn to cry "Cuming's love-grass"!

This notable contribution to the literature of the Australian arid regions is a desideratum for all botanical swagmen.

P. M. SMITH

PLANT CHEMISTRY

Phytochemical Phylogeny

Edited by J. B. Harborne. (Proceedings of the Phytochemical Society Symposium, Bristol, April 1969.) Pp. xiii+335. (Academic: London and New York, June 1970.) 110s; \$5.50.

THIS volume is the latest in the series devoted to the annual symposia of the Phytochemical Society. The book has a wide sweep with articles ranging from "The Origin of Plants" by P. Echlin, to "Secondary Constituents of Aquatic Angiosperms" by J. W. McClure, taking in *en route* such widely divergent topics as the controversial relationship between bacteria, blue-green algae and chloroplasts (N. G. Carr and I. W. Craig) and the straight organic chemistry of modern and fossil plant resins (B. R. Thomas). Two important contributions come from the Cell Research Institute and Department of

Botany, The University of Texas, Austin, the birthplace of modern phytochemistry in the United States; these contributions "Molecular Approaches to Population Problems at the Intraspecific Level" (B. L. Turner), and "Intraspecific Variation of Sesquiterpene Lactones in *Ambrosia* . . ." (T. J. Mabry) demonstrate how a beaver-like accumulation of data can be used imaginatively to open up new aspects of phytochemical phylogeny. R. L. Watts contributes a thoughtful and readable study of the basic principles, both genetic and biochemical, which underly the importance of studying proteins in relation to plant phylogeny. It is an appropriate time to spell out the reasons for continued studies on amino-acid sequences, now that sequencing is becoming almost a routine performance in modern laboratories devoted to protein chemistry. Watts's contribution is followed by a description by D. Boulter *et al.* of their sequence studies on cytochromes *c* from higher plants.

Both Echlin and Chaloner and Allen (palaeobotany and phytochemical phylogeny) point out the dangers which can befall the unwary in dealing with palaeobiology; for example, the ease with which it is possible to confuse artefacts with microfossils and the danger in ascribing the origin of a biochemical extracted from a coaly residue to the source plant: it could be a product of microbial degradation which had occurred before fossilization. Other chapters are concerned with sporopollenin (Shaw), the peculiar and extremely resistant polymer of the pollen wall which is thought to arise by polymerization of pollen carotenoids; with lipids of various photosynthetic organisms (B. W. Nichols), and with environment and enzyme evolution in plants (H. W. Woolhouse), a subject which needs considerably more study before its full implications are apparent. Finally, but by no means least, is a mature article by S. Bartnicki-Garcia on the importance of cell wall composition in fungal phylogeny; in relation to this his final conclusion that "Barring an unforeseen breakthrough in palaeomycology, the use of morphology in conjunction with biochemical data represents the only hope for reconstructing key events in the evolutionary history of the Fungi", is particularly significant.

I congratulate the participants in producing such an effective series of reports: the book represents phytochemistry at its best and any non-specialist reading this book is bound to be impressed by the distance modern phytochemistry has travelled during the past decade. The phytochemist of the 1970s is a person of wide interests who is successfully responding to the challenge of the new ideas developing in biology and chemistry, and who is meeting fresh problems with the intelligent use of modern equipment ranging from the mass spectrometer to the computer.

The indefatigable secretary of the Phytochemical Society, J. B. Harborne, has edited this volume with his usual professional thoroughness and has included four indices: author, chemical compound, genus and species, subject. The book seems singularly free from factual errors, although it seems inevitable that a book I review will have a carotenoid structure wrong (p. 5). The production of the book is up to the publisher's usual high standard.

T. W. GOODWIN

ELECTROCHEMISTRY

Modern Electrochemistry

An Introduction to an Interdisciplinary Area. By John O'M. Bockris and Amulya K. N. Reddy. Vol. 1: Pp. xxxii+1-622. 165s. Vol. 2: Pp. xxvii+623-1432. 190s. (Macdonald: London, July 1970.)

THESE two substantial volumes provide a novel and stimulating approach to the teaching of electrochemistry

as an interdisciplinary subject in a modern context. For many years, there has been a clear need for a teaching textbook with a non-specialist approach and with an emphasis on modern concepts, and this work is aimed at this gap. The authors maintain that the development of electrochemistry has been seriously retarded by an over-emphasis on the classical thermodynamic approach, and they seek, with crusading zeal, to correct this. As a result, a number of old battles are fought and the sound of this strife may well puzzle younger ears. The importance and utility of the Nernstian heritage are purposely neglected, and at times derided, and, in this sense, the book is unbalanced. The positive features of the work, however, are many and must be stressed.

The first volume gives a lucid and lively description of ionic solutions and it includes a large section on molten salts and glasses. The reader is led gently and expertly through a long series of interlocking discussions on the structure of water, ion-solvent interactions and ion-ion interactions in dilute and in concentrated solutions. The approach emphasizes modern, mechanistic descriptions, it is constructively critical and deals very effectively with the quantitative aspects. The material is built up gradually from an elementary level with a certain amount of repetition, to meet the needs of beginners and of those from outside the field who are seeking electrochemical expertise relevant to their own discipline; thus the book is long, but it is not tedious. Each chapter is divided into short, headed and indexed sections, and good lists of further reading material are provided at appropriate intervals.

The second volume deals in a similar manner with electrified interfaces and electrode processes. The content is generally excellent; for example, it includes a treatment of the semiconductor-electrolyte interface and of electrokinetic properties, and a discussion of electrocatalysis, electrodeposition, corrosion, fuel cells and batteries, but it is surprising in a modern text that no space is found for organic electrochemistry, an important and rapidly growing subject in which many practitioners are non-electrochemists in need of guidance. Much of the material lies close to the research interests of the authors, and, inevitably, their particular viewpoint on a number of topics is apparent. Their preference occasionally becomes obtrusive in the selection of scientists to be described as the most important contributors to the development of a particular branch of the subject.

The racy, colloquial style is easy to read and is seldom clumsy or obscure. The authors' predilection for coining new names is usually harmless, but there is no justification for neglecting the established terms cathode, anode, reduction and oxidation and substituting electron source electrode, electron sink electrode, electronation reaction and deelectronation reaction. The scope for electrochemistry and its importance in our technologically developing society is discussed at points throughout the books in a stimulating manner, although some of the examples used are very speculative. I am sure this work will substantially aid the vigour and lucidity of the teaching of electrochemistry at the undergraduate and postgraduate levels, and it will be welcomed by many research workers from other fields. A. BEWICK

BASIC QUANTUM MECHANICS

Quantum Mechanics

An Introduction. By J. G. Taylor. (Unwin Studies in Physics.) Pp. 207. (Allen and Unwin: London, June 1970.) 50s boards; 25s paper.

THIS book is meant to cover a one year course for students who are meeting quantum mechanics for the first time, and who will not necessarily specialize in theoretical

physics. This sensible aim is roughly that of the existing books by Matthews, Strauss and Ziock, for example. Taylor's book stands the comparison well. To begin with, its price is right: you get a lot of quantum mechanics for the price of the paperback edition. For the most part, it is a businesslike presentation of basic quantum mechanics. The book begins, very wisely these days, with a concise summary of classical mechanics. The Schrödinger equation and interpretative postulates are then introduced, and the standard one- and three-dimensional potential problems are mentioned. Time-independent and (an omission in Matthews) time-dependent perturbation theory is discussed, as in Strauss, in the context of atoms and molecules. The sixth chapter contains a much fuller account of scattering theory than either Matthews or Ziock offer, using the Green function method, and the book concludes with a pointer towards the Dirac equation and field theory.

To me the book seems to be particularly suitable for the student who is, in fact, going to specialize in theoretical physics; for such, the two or three page hints about variational principles, linear self-adjoint operators on the Hilbert space $L_2(\mathbb{R}^3)$, the rotation group and the analytically continued S-matrix would make sense. Although there are some useful analytical problems at the end of each chapter, there are very few numerical ones (as compared with Ziock or Strauss); also one might have reservations on whether the very brief discussion of non-relativistic spin formalism is adequate, especially when compared with Ziock's treatment. But Taylor's book, good value for money, is well worth considering.

I. J. R. AITCHISON

ABSORBED ENERGY

Photophysics of Aromatic Molecules

By John B. Birks. (Wiley Monographs in Chemical Physics.) Pp. xiii+704. (Wiley (Interscience): London and New York, May 1970.) 210s.

DR BIRKS is a well known experimental physicist in the field of phosphorescence and fluorescence in liquids and solids and he is especially interested in the relative efficiencies and rates at which these processes occur. Photophysics as opposed to photochemistry is not a word I have met previously. The author explains it as being concerned with the physical effects of non-ionizing radiation, but he has restricted himself largely to the subsequent history of the absorbed energy. He does not cover in any detail allied physical properties such as zero-field splitting and the electron resonance of triplet states, the absorption spectra of excited molecules, flash photolysis, and the like. Not that these subjects are totally ignored, but they are only mentioned where they relate to the principal themes of fluorescence, radiationless decay, internal conversion and phosphorescence. Photoconductivity, for instance, is covered in less than two pages.

"Aromatic Molecules" in the title also has a narrow meaning, because heterocyclic molecules, and therewith all σ lone pair excitations, are largely excluded. But in the selected field of benzene and the condensed aromatic hydrocarbons such as anthracene and their substituted derivatives the coverage is thorough. Much information is given in tabular form with consistent units and nomenclature, while the text comments helpfully on superseded work, and cases where impurities are suspected or imperfect techniques were used. Anybody requiring up to date numerical values of fluorescence or phosphorescence yields or life times, quenching constants, spectral peak energies or similar information for any carbocyclic aromatic molecule, its excimers, its donor-acceptor complexes in either crystal, glass or solution states is likely to find a reliable number here.

All this is excellent for those with closely related

interests to the author. I do not belong to this class, but am an interested worker in a neighbouring field who hoped to look over the hedge with interest and profit. In this I was a little disappointed. Birks himself says "Theory has been kept to the essential minimum", and while he is right not to repeat well known quantum theory, he does not use it much either. Paradoxically, the account would be easier really to comprehend if the concepts were less simply expressed. The simple perimeter free electron orbital model language chiefly used is less informative than state descriptions based on molecular point groups, especially when the former is introduced by figure 1-4, where the idea of nodal planes seems to be applied to many electron states rather than to one electron orbital. And while spin-orbit coupling is all important in radiative and radiationless singlet-triplet transitions, the discussion is largely qualitative, the energy term appearing twice as H_{so} and never as ζ l.s. or more complicated expressions.

This, then, is an important new monograph for which all active in the field will thank the author for his clear display of the known facts. It is an essential purchase for all relevant libraries. In considering its suitability for students, young or old, I am driven in honesty to report that I felt my knowledge had been increased more than my real understanding.

D. H. WHIFFEN

INTERNATIONAL MATHS

Mathematics Applied to Physics

Edited by E. Roubine. Pp. xvii + 610. (Springer-Verlag: Berlin and New York, 1970.) 58 DM; \$16.

A UNESCO sponsored congress on science teaching, held at Dakar in 1964, "agreed to recommend, as a priority measure, the preparation of a university syllabus of mathematics to meet the needs of physicists". This book is apparently the outcome of that decision, although it is clearly not a syllabus, being a collection of connected articles on various branches of mathematics, nor is it a textbook designed to meet the needs of such a syllabus, because several chapters are rather too concise to be easily followed by students quite unfamiliar with the material.

Each chapter is an admirably clear, up to date, and, in nearly every case, a readable account of its subject; chapter one confines itself to listing definitions and theorems; chapters four and ten are more restricted in scope than the rest and so are able to provide more leisurely treatments, even giving a few proofs; the remaining chapters find a compromise between these extremes. The chapters are largely independent of each other: the few cross-references give the impression of being afterthoughts.

The result of a collaboration between authors from seven countries, the book seems, perhaps inevitably, slightly uncertain of its level. To take a trivial example, it is not assumed that the reader knows what a differential equation is, although the term Hilbert space is used several times without definition.

The needs of physicists are seen in fairly classical terms: more than half of the book is devoted to differential equations. The final chapter, called "Quantum Mechanics", is considerably shorter than any of the others, and is, in fact, an elementary account of group representations and angular momentum in quantum mechanics.

If allowance is made for its classical emphasis, this book succeeds very well in providing a "syllabus plus some of the important details" covering the basic mathematical requirements of many branches of physics. It treats in an economical manner several important subjects, providing references to more detailed treatments where necessary, and so should also provide a useful work of reference.

J. UNDERHILL

Short Notices

Science, Industry and Society: Studies in the Sociology of Science. By S. Cotgrove and S. Box. Pp. xii + 211. (Allen and Unwin: London, July 1970.) 50s boards; 30s paper.

A HACKNEYED phrase in the sociology of science is that nearly every scientist who has ever lived is alive today. Stephen Cotgrove and Steven Box inform us of that in the opening sentences of the cover notes, the preface and chapter one of their book. That is a pity, because the book contains a much more original insight into some of the problems currently being faced by scientists—the influences of industry on the universities, the satisfaction and dissatisfactions of working in a laboratory and the gulf between academic and industrial scientists. The basis of the book is a series of questionnaires sent to scientists in universities and in industry, and the facts are presented in a comprehensive if rather dull manner. *Science, Industry and Society* stands, however, alongside Stephen Cotgrove's *Science of Society* as an important contribution to the sociology of science.

SI Units and Conversion Tables: A Practical Guide for Scientists. By M. N. Hughes, A. M. James, and N. R. Silvester. Pp. 23. (Machinery: Brighton, 1970.) 4s 6d.

THIS booklet is not designed to add more polemic to the discussion of the SI system but simply presents, in its uncompromising finality, a compilation of the symbols and units which constitute this system and the conversion factors relating it to its imperfect predecessors. The work seems to be aimed primarily at physicists and chemists, and yet anybody with editorial experience of the biological literature will know that the largest remaining concentration of the unconverted is to be found among the life scientists. This booklet should give them cause for introspection: not for long will they hold out against the schools on the one hand and technology on the other where the system is firmly implanted. One can comprehend but not condone the biologist's affection for units such as Å, the Svedberg and mmHg. With all respect, Ångström and his colleagues Gauss, Maxwell, Oersted and others have had a good innings; surely even the biologists can be prevailed upon to acclaim the new presidium: Newton, Weber, Joule and their friends.

Red Data Book. Vol. 5: Angiospermae. By R. Melville. (International Union for Conservation of Nature and Natural Resources Survival Service Commission: Morges, Switzerland, 1970.) SFr. 30; \$7.00; 60s.

THE status of many threatened plants is so uncertain that the International Union for Conservation of Nature and Natural Resources has deemed it wise to publish before completion the latest volume of its catalogue of rare and vanishing species. As more information becomes available further sheets will be prepared for this loose-leaf volume to add to the sixty-eight endangered angiosperms that Dr Melville has traced so far. Non-specialists need have no fear that this information will be beyond their comprehension; plants are described in the straightforward language of school botany. There are also, whenever possible, notes on distribution, habitat, biological value and so on. Remedial measures recommended include the preservation of Mount Athos in Greece as a national park free of grazing animals, so that *Centaurea athoa*, yellow Athos knapweed, may thrive again.

Correspondence

Semiconductor History

SIR,—I recently read the article, "Relationship between Science and Technology", by M. Gibbons and C. Johnson, published in the July 11 issue of *Nature* (227, 125; 1970). I found it very interesting. However, it contains several errors of fact.

In the section "Development of New Techniques" the statement is made that the need for radar detectors prompted much government sponsored work in the United States, principally at Purdue and Cornell Universities. In fact, the renaissance of the crystal detector was due to work on silicon carried out in Bell Telephone Laboratories prior to the war by R. S. Ohl, G. T. Southworth, A. P. King and others under the leadership of H. T. Friis. This work preceded the government programme by several years. The government programme in this country was centred at the Radiation Laboratory at the Massachusetts Institute of Technology as described by Torrey and Whitmer¹. Supporting programmes on germanium were carried out later at Purdue University under the leadership of the late Dr Karl Lark-Horovitz and on silicon at the University of Pennsylvania under Dr Frederick Seitz. I am not aware of a similar programme carried out at Cornell University. Finally, R. S. Ohl, H. C. Theuerer and myself were never employed at Purdue University. Our work in this field was all done at Bell Telephone Laboratories^{2,3}.

Yours faithfully,

J. H. SCAFF

Bell Telephone Laboratories Inc,
Murray Hill,
New Jersey 07974,
USA.

Pop Charts for Science

SIR,—Mr E. Garfield's paper (*Nature*, 227, 669; 1970), though rational, is disturbing. While the quotation-coefficient of a paper, if one may call it that, is to some extent a measure of the use made of its content, it would be unfortunate if the support a scientific author receives were to be made conditional on his current position in the charts. One can imagine reasons why papers in industrial chemistry might rate higher than those in, say, topology or palaeontology. In fact, were we to confine our analysis to papers published in China, the chart leader would no doubt be Chairman Mao.

In fact, the analogy from pop music raises the covers from some of the abuses we might expect (and even, while waiting for our Nobel Golden Disk, indulge in): commercial concerns dedicated to lobbying, so that our rating might be raised? Promotional quotation-data on the relative one-upmanship of particular journals? In California nothing is impossible.

We must all accord respect to Mr Garfield's ingenuity in devising a means whereby an unskilled staff can score

publications for reference: that our capacity for publicity should become a measure of our worthiness of support is, however, a trifle *simpliste*. I am reminded that, according to anecdote, one of the centurions supervising the Crucifixion remarked to his comrade, "I hear he was a great teacher". "Yeah", replied the other, "but he never published anything." The fact that his graduate students did would elude Mr Garfield's net.

Yours faithfully,

ALEX COMFORT

University College London,
Gower Street,
London WC1E 6BT.

Disputed Pronoun

SIR,—Hammerton¹ has attempted to refute Chomsky's² assertion that, in the sentence "Learning that John had won the race surprised him", the pronoun *him* cannot refer to John. The refutation, claimed to be significant at the level of one part per million, was based on the responses of twenty people who read an *ad hoc* paragraph containing the sentence in question. The respondents all felt sure that, in the given context, *him* referred to John. It is my contention that it was an agreement of desperation. If *him* did not refer to John the paragraph would be meaningless. Hammerton's subjects had the choice of ignoring Chomsky's rule or admitting that they did not understand what was otherwise a trivial paragraph.

I also have done a poll. Hammerton's paragraph was typed and offered to twelve subjects to read. They were then asked what they thought of the penultimate sentence (the one in question). A typical reply was, "I thought I was understanding the passage till I got to that sentence. Then I had to start the paragraph again to verify who John and Bill were". All twelve readers agreed that substitution of *he* for *John* would improve the sentence and make the paragraph clear on first reading.

However, when a name denotes both a person and his public image Chomsky's rule may be relaxed. For example, in the sentence, "Learning that Heath had won the election surprised him", *him* can refer to Mr Heath, but not *Heath*. English permits Mr Heath to say "Heath won" but it does not permit John to say "John won" unless John is a king or a second person with that name.

After we understand the linguistics of well constructed sentences will be early enough to tackle sentences like this one or Hammerton's paragraph.

Yours faithfully,

EDWARD ARGYLE

Dominion Radio Astrophysical Observatory,
Box 248,
Penticton, BC, Canada.

Obituaries

Dr H. Boyko

HUGO BOYKO, widely known as an ecologist of arid regions and as the founder and president of the World Academy of Art and Science, died in Israel on May 26, 1970. He was 78.

Boyko's early academic associations were with the University of Vienna, but before the Second World War he emigrated to Palestine. His early publications gave a comprehensive picture of what was then called "plant sociology". After emigration his preoccupation with the ecology of arid zones in the Mediterranean area first led him to investigate the role of plants as quantitative climate indicators and the geo-ecological law of distribution. He was particularly interested in the relations of plant ecology with hydrology and hydro-engineering, and indeed his later work concentrated chiefly on the use of salt water for the reclamation of arid zones. In 1950 he was appointed by UNESCO as a member of the international advisory mission for arid zone research, and he continued to investigate the possibilities of sea-water irrigation for the rest of his life. One practical consequence was the transformation of the desert area of Elath into a garden and resort. Boyko's ideas were set out in two books, *Salinity and Aridity* (1966) and *Saline Irrigation for Agriculture and Forestry* (1968).

In the course of his travels for this purpose, he was able to assemble a large herbarium, which covered specifically the plants of the Middle East.

Boyko's humanitarian leanings were also made explicit in his desire for international cultural cooperation. In 1956 he gave a lecture on the need for an international academy of arts and sciences at the International Conference on Science and Human Welfare in Washington. By 1960 his efforts had culminated in the founding of the World Academy of Art and Science, which has now grown to include more than three hundred fellows chosen on the strength of their intellectual achievements and their concern for human welfare. As president of the academy, Boyko was taking part in this year's conference on the environment and on society in transition, in New York, just a few weeks before he died.

Professor S. J. Folley

SYDNEY JOHN FOLLEY, FRS, died in hospital on June 29. He was 64 years old. He had been head of the physiology department of the National Institute for Research in Dairying (University of Reading) since 1945 and a research professor of the university since 1964.

He was born in Swindon, Wiltshire, and received his early education in that county. With a county university

scholarship he entered the University of Manchester in 1924, graduating in 1927 with first class honours in chemistry and with the award of the Mercer Scholarship.

After a year's postgraduate research in colloid chemistry he transferred to the physiology department and became personal assistant to Professor H. S. Raper. His first official university post was that of assistant lecturer in the biochemistry department at Liverpool. In 1932 he went to the NIRD as research assistant to the recently appointed physiologist, who resigned in 1933, leaving Folley and a young technician as the entire staff of the embryo physiology department.

Folley's interest in the endocrinology of mammary function in relation to dairying was soon aroused, and with improving laboratory and animal facilities and increasing scientific assistance his original and active mind began to probe deeply into this field. He was given charge of a section of lactational physiology in 1939. This evolved, after the war, into a full physiology department with a staff of twelve and most of the facilities necessary for experimental work on animals of all sizes.

There followed in his department an exciting period of research in which the effects of thyroxine and of pituitary hormones on milk quantity and quality, and also those of stilboestrol on mammary growth and milk production in virgin heifers, were quantitatively studied and the new knowledge firmly established. It was also demonstrated ("the first major experiment by the use of ^{14}C in Britain") that the short-chain fatty acids of milk fat were, in the ruminant, built up in the alveolar cells of the udder largely from the acetate taken up from the rumen into the circulating blood. Valuable findings were also made on the minute structure of the milk-secreting tissues and on the neuro-endocrine control of milk ejection based on a delicate method devised in his laboratory for the assay of the milk-ejection hormone, oxytocin.

These and many other physiological and biochemical problems were successfully attacked by Folley, assisted by his colleagues and visiting scientists, bringing distinction to his department, his institute and himself. He was elected a Fellow of the Royal Society in 1951 and his work has received further wide recognition both at home and abroad. In 1964 he was made an honorary doctor of veterinary medicine at the University of Ghent and he received the Dale Medal in 1969.

In his later years his failing eyesight, which deteriorated rather rapidly so that he was unable to read or work with his own hands in the laboratory, made him increasingly dependent on colleagues. But by means of tape records and other aids he was able to keep well abreast of advances in his field of research, and the successful pursuit of his work to the end was an exemplary manifestation of his courage and the devoted support of his wife.

Announcements

University News

Professor Robert E. Davies, professor of biochemistry at the University of Pennsylvania School of Veterinary Medicine, has been appointed Benjamin Franklin professor of molecular biology.

Dame Mary Cartwright, reader in the theory of functions in the University of Cambridge, will visit the Institute of Mathematics of the Polish Academy of Sciences and other Polish universities as Royal Society Leverhulme visiting professor.

Dr J. C. Amson, University of St Andrews, has been awarded a research grant by the Centre for Environmental Studies, London, to study the application of advanced mathematical theories to the structure, growth and stability of urban systems.

Dr D. Lack, director of the Edward Gray Institute of Field Ornithology, University of Oxford, has been appointed Royal Society visiting professor to the University of the West Indies, Jamaica, for the academic year 1970-71.

Appointments

Professor John Heslop-Harrison will succeed **Sir George Taylor** as director of the **Royal Botanic Gardens, Kew**, when Sir George retires in May 1971.

Mr Robert Wood has been appointed director of studies at the Overseas Development Institute in succession to Dr Tom Soper.

Mr W. E. Jones, chief agricultural adviser to the Ministry of Agriculture, Fisheries and Food, has been appointed first director general of the MAFF Agricultural Development and Advisory Service which is to start on March 1, 1971. **Major E. S. Dobb**, at present director of the Agricultural Land Service, and **Mr W. R. Smith**, at present director of the National Agricultural Advisory Service, will be deputy directors general of the new service.

Miscellaneous

The **J. J. Thompson award** of the **Institution of Electrical Engineers** has been won jointly by **Dr H. G. Lubszynski**, **Dr B. J. Mayo**, **Mr J. Wardley** and **Mr N. C. Barford**, all of EMI, for their paper "New All-electrostatic Vidicon".

Professor B. E. C. Nordin, head of the MRC Mineral Metabolism Unit, Leeds General Infirmary, has won the first **International Health Foundation award**, for his paper "The Clinical Significance and Pathogenesis of Osteoporosis."

The **Hanbury Memorial Medal** of the Pharmaceutical Society of Great Britain, awarded biennially in memory of the nineteenth century pharmacist Daniel Hanbury, has been won by **Professor R. B. Woodward**, Donner professor of science at Harvard University. Professor Woodward will deliver the memorial lecture on "Recent Advances in the Chemistry of Unnatural Products", at the School of Pharmacy, University of London, on November 4.

The Council of the Royal Society has awarded four **Royal Society Leverhulme scholarships**: to **Mr Patrick Duncan**, University of Oxford, to study the habitat utilization of the topi in the Serengeti National Park; to **Mr B. J. T. Jones**, University of Cambridge, to investigate at Mount Stromlo Observatory phenomena in the southern skies relating to the formation and properties of galaxies; to **Mrs P. J. Edwards**, University of London, to study the freshwater fishes of New Guinea; and to **Mr D. J. Maberley**, University of Oxford, to carry out an ecological investigation in the mountains of East Africa and Madagascar of thick stemmed vegetation with special regard to its origin.

ERRATUM. In *Nature* of August 29, the article entitled "Membranes Dismembered" (227, 888; 1970) was attributed to our Microbiology Correspondent. It was, of course, by our Molecular Biology Correspondent.

ERRATUM. In the review, "Weddell's Voyage South", by H. G. R. King (*Nature*, 227, 973; 1970), the words "chronometer sand tables" in lines 16 and 17 of the second paragraph should read "chronometers and tables", and the word "Indies" in line 24 in the same paragraph should read "Indians".

International Meetings

September 7-12, **Hormonal Steroids**, Hamburg (Dr J. Tamm, 2 Medizin, Universitätsklinik, Martinistrasse 52, 2000 Hamburg 20, Germany).

September 9-11, **British Association for Crystal Growth Conference**, Bristol (Dr D. Elwell, Physics Department, Portsmouth Polytechnic, Park Road, Portsmouth, Hampshire).

September 9-11, **British Pharmacological Society Meeting**, London (Dr P. J. Piper, Department of Pharmacology, Royal College of Surgeons, Lincoln's Inn Fields, London WC2 3PN).

September 14-16, **Institute of Electrical and Electronics Engineers Group on Antennas and Propagation Meeting**, Columbus, Ohio (William D. Stuart, Battelle Memorial Institute, Columbus Laboratories, 505 King Avenue, Columbus, Ohio 43201, USA).

September 15-17, **US National Committee of URSI Meeting**, Columbus, Ohio (William D. Stuart, Battelle Memorial Institute, Columbus Laboratories, 505 King Avenue, Columbus, Ohio 43201, USA).

September 17-19, **Prostaglandins**, New York (The Executive Director, New York Academy of Sciences, 2 East Sixty-third Street, New York, NY 10021, USA).

September 22, **Technology and the Environment**, London (Information Department, Confederation of British Industry, 21 Tothill Street, London SW1).

September 22, **Analysis and Control of Pollution**, Bristol (Society for Analytical Chemistry, 9-10 Savile Row, London W1X 1AF).

September 24, **Air Coolers**, London (Conference Publicity Section, Institution of Mechanical Engineers, 1 Birdcage Walk, Westminster, London SW1).

September 24, **The Feeding Habits of Schoolchildren**, London (D. J. Vogler, The National Dairy Centre, 5-7 John Princes Street, London W1M 0AP).

September 29-October 2, **Trunk Telecommunications by Guided Waves**, London (Manager, Conference Department, Institution of Electrical Engineers, Savoy Place, London WC2R 0BL).

September 30, **Spectra and Structures of Molecular Ions** (Faraday Lecture), London (Dr John F. Gibson, The Chemical Society, Burlington House, London W1V 0BN).

October 5-9, **Electron Microscopy Society of America Meeting**, Houston (Carl Tessmer, Section of Experimental Pathology, University of Texas MD Anderson Hospital and Tumor Institute, Texas Medical Center, Houston, Texas 77025, USA).

October 5-9, **Plutonium and Other Actinides**, Santa Fe (F. W. Schonfeld, Los Alamos Scientific Laboratory, PO Box 1663, Los Alamos, New Mexico 87544, USA).

October 13, **Profit from Tribology**, Glasgow (Ministry of Technology, Millbank Tower, Millbank, London SW1).

October 13-16, **Population 70—Family Planning and Social Change**, Tokyo (The Information Officer, International Planned Parenthood Federation, 18-20 Lower Regent Street, London SW1).

October 20-23, **Clean Air Exhibition**, Southport (National Society for Clean Air, 134-137 North Street, Brighton, Sussex).

October 21-22, **British Coal Utilization Research Association Open Days**, Leatherhead (Public Relations Officer, BCURA, Randalls Road, Leatherhead, Surrey).

October 22-23, **Organic Microchemistry and its Applications**, Salisbury (Society for Analytical Chemistry, 9-10 Savile Row, London W1X 1AF).

Sabbatical Itinerants

British Diary

Monday, September 7

Basic Concepts in Modern Control Theory (five-day vacation school) Institution of Electrical Engineers, at the University of Birmingham.

Control Mechanisms of Growth and Differentiation (five-day symposium) Society for Experimental Biology, in conjunction with the Society for Developmental Biology, at Eliot College, University of Kent, Canterbury, and Wye College (University of London), Wye, Ashford, Kent.

Computational Physics (three-day conference) Institute of Physics and the Physical Society, at Imperial College, London SW7.

Third International Broadcasting Convention (five days) Institution of Electrical Engineers, and the Institution of Electronic and Radio Engineers, at Grosvenor House, London W1.

Tuesday, September 8

Optical Techniques for Investigations in the Upper Atmosphere (three-day conference) Institute of Physics and the Physical Society, at the University of Exeter.

Wednesday, September 9

Second Particle Size Analysis Conference (three days) Society for Analytical Chemistry, at the University of Bradford.

The Degradation of High Polymers (informal discussion) Faraday Society, at the University of Surrey, Guildford, Surrey.

Sunday, September 13

Second International Conference on Raman Spectroscopy (five days) at New College, Oxford.

Monday, September 14

Aerodynamic Noise (four-day symposium) Loughborough University of Technology, in collaboration with the British Acoustical Society, and the Royal Aeronautical Society, in the Edward Herbert Building, University of Technology, Loughborough.

Photoionization Phenomena and Photoelectron Spectroscopy (three-day conference) Institute of Physics and the Physical Society, Atomic and Molecular Physics Sub-Committee, in collaboration with the Theoretical Chemistry Group of the Chemical Society, at the University of Oxford.

The Economics of Ammonia Production (two-day international symposium) Fertiliser Society, at Shell Centre, London SE1.

The Physics of Non-Crystalline Solids (third international conference) at the University of Sheffield.

HOW TO BUY NATURE

Volumes start in January, April, July and October, but subscriptions may begin with any issue.

The direct postal price per subscription for one copy of NATURE each week is:

*12 MONTHS (52 issues and 4 indexes)

Great Britain and Eire.....£14 0 0 each

United States of America.....(by air freight).....\$48 each

Canada.....(by air freight).....\$52 each

Elsewhere overseas by surface mail.....£14 0 0 each

(Charge for delivery by air mail on application)

*Shorter periods pro rata. (Minimum three months.)

Way Forward, No Way Back

WHAT is happening in the developing countries? And what can be done to make the transition between the past and future at once smoother and more civilized? Two conferences in the past few days have raised important and contrasting issues. At Aspen (see page 1083) it seems to have been broadly agreed by a conference composed largely, although not exclusively, of liberally minded people from developed countries that one of the most urgent problems is the control of population growth. At the British Association in Durham, however, Professor T. A. I. Grillo of Ibadan, Nigeria, has roundly stated that he doubts whether Africa "has a population problem" and even hints that the whole issue may be a plot in which the advanced countries of the world lead the developing countries up the garden path (see page 1081). At Aspen, people also seem concerned that no amount of economic assistance to the developing nations should prevent them from following their own individual paths to prosperity—or even something other than prosperity if they choose; the doctrine of the multi-valued society (whatever that may mean) is to the fore. In Durham, by contrast, Professor Grillo stoutly defends the decision of the Nigerian government to follow substantially the pattern of university development now classical in the United States, the United Kingdom and Western Europe, and even goes one better by insisting that Nigerian medical schools will "not fall into the trap" which seems to him to be represented by attempts at the reform of the medical curriculum now being made in the United States and Britain. On the face of things, of course, Professor Grillo should know best, and there is, in any case, a profound lesson in his declaration that the best way of helping other people is first to find out what other people want. Yet there is also much in what the Aspen people say.

To begin with, Nigeria is exceptional. It has a population (60 million) larger than that of Britain and a strong tradition of university teaching. In the old days of the British Commonwealth (within which Nigeria was always a protectorate, a slightly different entity from a colony), British civil servants always considered their work there to be superlative. Great things were expected. Paradoxically, the civil war (now mercifully at an end) has demonstrated that these brave hopes were justified. The country, after all, is still intact after a domestic tragedy which is by all accounts comparable with that which ravaged the United States a century ago. Moreover, Nigerians of all parties, possibly with the exception of those from the north, will probably in the long run be glad that the civil war was eventually resolved without sub-

stantial assistance from outside, East or West. To be sure, it would be folly to generalize from this example to the proposition that civil war is a way of becoming strong—most countries would not have survived what Nigeria has been through. Most countries even at comparable stages of economic and industrial development, lacking as they do the oil that has made Nigeria viable, would have found the experience to be fatal. To say this is not in any sense to diminish the importance of what has happened in Nigeria, but merely to suggest that the example is not entirely representative. Yet there is something in Professor Grillo's demeanour that deserves to be noticed outside Nigeria.

This, it seems, is what the people at Aspen have acknowledged with their declaration that ways must be found of allowing developing nations to develop in their own ways. The truth may be that developing nations prefer—or find it convenient—to follow the classical path of development in the industrialized parts of Western Europe, but that is not an external constraint but an act of will. For, as it turns out, the developing nations are much more in charge of their own destinies than they were a decade ago. In some places, economic and social difficulties have become worse, but the benefits of a decade or more of independence and of educational development have begun to accrue. With this development has come such a diversity within what used quite inappropriately to be called the underdeveloped world that generalizations are almost always offensive as well as wrong. This is a transition to be reckoned with.

So does it follow that the developing nations can now be left to fend for themselves? To many people in industrialized societies, this is a tempting speculation. It is also dangerous on at least two counts, one positive and familiar—one a product of the new confidence of the developing nations.

The economic gap between the rich and poor countries is as much a source of danger now as ever, and for a variety of reasons. The old notion that the envy of the developing nations for their richer neighbours might lead to conflict of the kind which set the Huns against the Roman Empire is far-fetched, but there is no doubt that economic disparities breed international tension over issues such as tariffs, nationalization and currency control. There are also powerful arguments related to the view that everybody would be richer in a larger market, which boils down to saying that the economic self-interest of industrialized societies requires that the process of development should be hastened. In this sense, foreign aid should be regarded not as charity but as long-term

investment in prosperity for nations of all kinds, at present either rich or poor. By the same token, there should be a general welcome for the prospect of a much more easy-going interchange of people and ideas between the developing and the developed nations. Just as a larger market is richer, so a larger intellectual community is more powerful and self-stimulating. In short, the case for foreign aid and technical assistance has not diminished.

But why, then, do the Aspen people and Professor Grillo differ on the importance of the population growth in the developing nations? To be sure, Latin America and South-east Asia are the population blackspots. By contrast, such imbalance as there may be between people and food in Africa is as much a consequence of ignorance as poor agriculture. That said, however, the belief that Africa can snap its fingers at the growth of population is mistaken, for it is now, as ever, a real problem to balance present growth of population and prosperity. In many advanced societies, it has become common for individual families to make this kind of comparison for themselves, and one consequence has no doubt been the comparatively rapid fluctuation in recent years of the birth rate in countries such as the United States. Even if countries like Nigeria had secretly chosen as long-term goals the attainment of a very large population, it might nevertheless be sensible to aim in the immediate future at the comparative economic

prosperity (and the declining death rate that would result) that a restricted birth rate would bring. That, in short, is the case for a restriction of the rate of growth of population. If the advanced nations were malevolently disposed towards the rest of the world, the chances are that they would preach procreation.

If malevolence is absent, however, indifference is rife. One of the fearful developments in the past few years is the preoccupation of the developed nations with their own affairs. The American involvement in South-east Asia is a typical example—military assistance, so to speak, has replaced technical assistance. But the problems of American society are also distracting, with the result that there is very little hope that Congress will easily be persuaded, before 1972, that the purse-strings should be loosened. Indeed, the way things are going in Washington, Congress may yet devise a means of taking away with one hand what it has given with the other by erecting tariffs to keep from the United States market goods which have been manufactured in developing countries. This will be cruel and absurd. And unhappily there is at present very little sign that the nations of Western Europe are ready to fill the gap. Here again, preoccupations with the European Economic Community or with the relationship of East and West are distracting. On the whole, the balance lies towards gloom, not optimism.

Over the Hill into the Sunset

THE British Association continues to defy the prophecies of those who expect that it will soon die, but only by the narrowest of margins. The meeting this year at Durham has been a considerable success, at least as far as the composition of the meetings goes, but there is no mistaking the signs of infirmity in the ageing limbs. The ructions this year have taken different forms, but the causes of discontent remain what they have been for several years. The organization is poor. The programme, like the curate's egg, is good only in parts. Certainly it is not firmly planned, the efforts of the new planning committee notwithstanding. And the hierarchy is top-heavy, too slow to move with events, now timed with hour-glasses, not calendars. As a result, the association for all its splendid past is much less influential than it could be. Whom the gods will destroy, they first make effete—this seems to be the moral.

The immediate causes for alarm, open secrets every one, add up to make a sombre picture. There is the threat of a severe financial crisis. Half of the association's regular income of £50,000 comes from government departments as subventions for the worthy work

of bringing the message of science to young people and for introducing many of them to technology. There is too little elasticity in the remainder for the association to be able to accommodate inflation. The crying need is for an independent source of income, but it appears instead to have responded to a serious situation by economizing on staff in a manner unlikely to command the affection of those still on the payroll. There has also been, at Durham, the constant skirmishing between chairmen of scientific meetings and the eloquent and sometimes articulate members of the British Society for Social Responsibility in Science: impending law-suits apart, there is a case for thinking that the BSSRS had the better of the encounter. Certainly the dissidents made the meetings lively. Predictably, perhaps, the association responded as would an elephant or—more worrying—a dinosaur.

So why not look the other way and let the breath ooze slowly from the collapsing frame? There are several reasons for taking care. For one thing, the British Association has its roots in the years at the beginning of the nineteenth century when the Royal Society was moribund for lack of discrimination and

when the young men who laid the foundations of Victorian science were crying out for a forum in which to talk to each other. The association's achievement has been great. It has been in turn a learned society, a means of influencing policy on scientific administration and research, a coliseum for the confrontation of ideas (as with the row between Huxley and Wilberforce on Darwinism or the puzzling towards the end of the century about the relationship between electromagnetism and relativity), and a device for the enlightenment of many people who wish to learn about science or merely keep up to date as well as an active source of pleasure for those who attend the annual meetings. More recently, there have been cheerful if shoestring attempts to interest young people in these kinds of things. Maybe the role of the association as a place in which new results in scientific research are brought before the scientific profession, is no longer necessary, but there is no mistaking the honest goodwill that serves still to keep the association's head just above the water. It would, of course, be folly to waste such an asset, especially now that there has emerged more clearly than ever a need for level-headed discussions of social issues to which the supposedly socially responsible scientists have this past week somewhat irresponsibly drawn attention.

So what is to be done? That change should turn out to be desirable in changing circumstances should not be a surprise. The modern world abounds with illustrations of how hallowed institutions must either change with the times or be overtaken. As luck will have it, and if only the association would see it, the changes required of this cumbersome framework are a good deal less drastic than many institutions have been compelled to undergo. And the overriding need is to have a clear strategy for the years ahead. What is the association trying to accomplish? The enlightenment of a thousand or so members at the annual meeting, worthy cause though it may be, is not a sufficient excuse for continuing to exist. Even the work with young people is not a sufficient justification—quite separate organizations might accomplish the same ends. If the association is sensitive at all to its great traditions, it will continue into the present the influence which it could exert a century ago on the way in which science as a whole is accepted into public life. There is no shortage of important matters to be dealt with—the world is full of them.

The directions in which change could be sought within the British Association are also, as luck will have it, plain for all to see—if they have the will. Although money does not grow on trees, there is no reason why the association should not add to its activities in ways that will allow it to prosper. Other such bodies publish books, undertake research and other investigations of public importance, and sometimes even find themselves able to allow members to attend annual meetings and the like without levying steep charges on them. With ingenuity, wit and a little energy, it should be possible for the association to put its books in order without having to pass

around the begging bowl in the way which seems at present to be the closest approximation to financial management.

A good deal of the necessary reforms would be more easily accomplished if the organization of the association were not a kind of fossil record of its history. Over the years, hierarchies of committees have grown up in such a way that nobody can tell where power lies. With the convention that the president should be a luminary plucked from outside—a Nobel prize-winner if possible, but otherwise somebody on whom public honour has already fallen—the permanent general secretary of the association should be the one not merely to keep the association running smoothly but to hammer out policy and to present the association's case to the outside world. But is this man intended to be a leader or merely a servant of the bureaucracy? The association has never been clear in its mind on this, with the result that there is a small group of general officers whose function seems to be to make sure that the general secretary toes some imaginary line in the conduct of the association's business. The general conduct of policy, on the other hand, is supposed to reside with the council, much larger than efficiency requires and, in any case, less able than it should be on account of its part-time character to keep a constant watch on the association's business. Furthermore, a skilled president can always hope to keep at least one step ahead of his council, but there are always dangers that even he might be overruled by either the body known as the general committee or, failing that, by the General Assembly—the committee of the whole, as the Americans would say. If this division and scattering of power were not a sufficient offence against the principles of good management, however, there is a further complication. The sections of the association normally responsible for the specialist parts of the scientific programme have ill-defined but substantial degrees of autonomy (which is one reason why the scientific programme never quite hangs together). Nobody knows how the relationship between the sections and the rest of the association is determined, but the relationship is beyond doubt archaic. One of the most urgent needs is that this complicated organization should be simplified. On the face of things, it is hard to see how the work can be done entirely from within the association.

In much the same way, responsibility for the routine work of the association is divided between the full-time professionals at head office and the small arms of volunteers throughout the length and breadth of Britain who spend their precious time addressing envelopes to each other. Although a simpler organization could drastically reduce the waste of energy involved, greater professionalism in the conduct of the association's business would probably make necessary an increase of staff and not the reduction on which the association has somewhat precipitately embarked.

Is there, then, a chance that all this can be mended from within? It is at least a sign of grace that the association has decided at long last to set up an inquiry

into its own affairs. High time is what people will say. But everything depends on how the inquiry is carried out. How much in the thrall of the existing hierarchy of committees and officials will it be? There is the strongest case for asking that the chairman of the inquiry should be an independent well-wisher from outside the immediate circle in which power is at present distributed. It is also essential that the inquiry should be quick. If by this time next year the association is not in better shape, there is a serious risk that it will bleed to death.

100 Years Ago

And looking back through the prodigious vista of the past, I find no record of the commencement of life, and therefore I am devoid of any means of forming a definite conclusion as to the conditions of its appearance. Belief, in the scientific sense of the word, is a serious matter, and needs strong foundations. To say, therefore, in the admitted absence of evidence, that I have any belief as to the mode in which the existing forms of life have originated, would be using words in a wrong sense. But expectation is permissible where belief is not; and if it were given me to look beyond the abyss of geologically recorded time to the still more remote period when the earth was passing through physical and chemical conditions, which it can no more see again than a man can recall his infancy, I should expect to be a witness of the evolution of living protoplasm from not living matter. I should expect to see it appear under forms of great simplicity, endowed, like existing fungi, with the power of determining the formation of new protoplasm from such matters as ammonium carbonates, oxalates and tartrates, alkaline and earthy phosphates, and water, without the aid of light. That is the expectation to which analogical reasoning leads me; but I beg you once more to recollect that I have no right to call my opinion anything but an act of philosophical faith.

As regards the second problem offered to us by Redi, whether Xenogenesis obtains, side by side with Homogenesis; whether, that is, there exist not only the ordinary living things, giving rise to offspring which run through the same cycle as themselves, but also others, producing offspring which are of a totally different character from themselves, the researches of two centuries have led to a different result. That the grubs found in galls are no product of the plants on which the galls grow, but are the result of the introduction of the eggs of insects into the substance of these plants, was made out by Vallisnieri, Reaumur, and others, before the end of the first half of the eighteenth century. The tapeworms, bladderworms, and flukes continued to be a stronghold of the advocates of Xenogenesis for a much longer period. Indeed, it is only within the last thirty years that the splendid patience of Von Siebold, Van Beneden, Leuckart, Küchenmeister, and other helminthologists, has succeeded in tracing every such parasite, often through the strangest wanderings and metamorphoses, to an egg derived from a parent, actually or potentially like itself; and the tendency of inquiries elsewhere has all been in the same direction. A plant may throw off bulbs, but these, sooner or later, give rise to seeds or spores, which develop into the original form. A polype may give rise to Medusae, or a pluteus to an Echinoderm, but the Medusa and the Echinoderm give rise to eggs which produce polypes or plutei, and they are therefore only stages in the cycle of life of the species.

An extract from the opening address of T. H. Huxley to the 1870 meeting of the British Association, held at Liverpool. From Nature, 2, 404, September 15, 1870.

OLD WORLD

BLACK ARROW

Crisis of Confidence

THE failure of Black Arrow to launch a satellite last week has placed the Ministry of Technology in an embarrassing position. Should last week's firing be repeated, making further inroads into the stock of rockets on order, or should the programme go ahead as planned, in which case a £2 million satellite will be risked in a firing early next summer? The heart-searching behind this decision is one of the penalties to set against the shoe-string budget on which the Black Arrow is based—£3 million this year, gradually rising to £5 million during the next two years. Unsuccessful firings are now rapidly eroding the programme. In June last year the first Black Arrow with a dummy third stage went off course after fifty seconds of flight because of a fault in the control system and had to be destroyed. That meant that instead of the first orbital attempt in March this year there had to be a repeat of the earlier firing. Now the postponed orbital attempt has failed, apparently because of a fault in the pressurization of the second stage oxidant tank.

The chronology of the firing was as follows. First, a fault at the Gove tracking station, northern Australia, caused a postponement on September 1 in the last few minutes of the countdown. Gove is an ELDO tracking station that was due to be closed down now that launchings of the Europa rocket are to be from French Guiana, but was kept on for the Black Arrow launch. Although tracking by Gove is not essential, it gives a useful cross-check. The fault was in the computer that steers the aerial, and was discovered after the nominal flight path was fed in just before launch. Because the computer could not be put right within the duration of the launch window, the firing was postponed to the following day, and then delayed a further 2½ hours because of weather conditions. The faulty pressurization caused the second stage engines to stop thirteen seconds early, so that the spent stage crashed only 800 miles north of Woomera, 1,400 miles short of the expected impact point. Although the third stage subsequently seems to have worked perfectly, too much velocity was lost for the satellite to go into orbit.

To make matters worse, both failures of Black Arrow were due to faults in what were believed to be some of the soundest parts of the rocket. Basically a nitrogen bottle and a valve, the pressurization was thought to be simple and reliable. It now looks as if the sealing up of the highly successful Black Knight two-stage research rocket has not gone as well as the Ministry of Technology must have hoped when it earmarked only three Black Arrows for development firings. These are now spent, and there is no possibility of another development firing before next summer when the X3 satellite is due to be launched, chiefly to test new satellite instrumentation. It is too early yet to say what effect the failure will have on the ministry's hopes of selling Black Arrow rockets to ESRO, although they must be extracting some crumbs of comfort from the news that their competitor, the French Diamant rocket, is said to be running into trouble with excessive vibrations imposed on the payload.

What a sad start for Mr A. Goodson, who took over from Mr R. H. W. Bullock as head of the Space Division at the Ministry of Technology on the morning of Black Arrow's failure.

All to Go at Gove

THE down-at-heel air that surrounds Britain's Black Arrow space programme is well illustrated by the news that the ELDO tracking station at Gove, Australia (where a computer failure caused the first postponement of last week's space shot) is up for auction. The sale will take place on October 20. All the station's equipment is to be auctioned off including presumably the errant computer and tracking dish that figured in last week's Black Arrow launch. For the Black Arrow firing last week the Ministry of Technology borrowed Gove from ELDO. Its function was to monitor the performance of the third (apogee motor) stage of the launch, a task that should in future be carried out by an onboard inertial apparatus on flight test for the first time last week. Some of the ELDO equipment in Australia is to be shipped to the Kourou range in French Guiana, where the remaining ELDO launchings will take place, but all of the Gove material is for disposal at the October auction. ELDO, chronically short of funds, hopes in this way to recoup some of its capital outlay. The sale is being widely canvassed among interested parties in the area—presumably the Japanese, the Americans and the various military establishments that make use of Australia. By a deft piece of public relations the announcement of the Gove auction occurred the same day as the postponement of the Black Arrow launch due to the failure in the Gove equipment.

DEFENCE

No Rest in Arms Race

WHILE the preliminary rounds of the Strategic Arms Limitation Talks (SALT) were going on earlier this year, the nuclear arms race showed little signs of slowing down. The Soviet Union, during the twelve months ending on June 30, 1970, added 250 new land-based and 120 sea-based intercontinental ballistic missiles to its arsenal, thereby putting it ahead of the United States in terms of sheer numbers of land-based missiles. But the United States continued to develop the Minuteman-3 and Poseidon multiple independent re-entry vehicles (MIRV) and a decision to expand the "safeguard" antiballistic missile system has just been taken by Congress. These developments, mapped by the Institute of Strategic Studies, provide ample proof that the policy of assured destruction capacity which has guided the defence policies of the United

States and the Soviet Union during the 1960s has continued into the 1970s, SALT talks notwithstanding, and these two powers alone are planning to spend \$114,778 million on their defences this year (*The Military Balance 1970-71*, ISS, 13s).

While the nuclear merry-go-round continues at this alarming rate, and the two chief military powers seem reluctant to step off, other powers are anxious to join in. The launching of China's first satellite in April this year inevitably increased speculation that Chinese missiles may soon be capable of hitting cities in the United States but, according to the Institute of Strategic Studies, there is still no evidence that the country has yet developed operational missiles, and its ability to deliver nuclear weapons is still limited to early bombers. Nevertheless, the long-term threat of that development seems to have provided a powerful lever for getting the appropriations for the safeguard system accepted by Congress.

As far as conventional forces are concerned, the Institute of Strategic Studies points out that the Warsaw Pact countries have some 11,000 more tanks and 2,000 more tactical aircraft in Europe than the NATO countries have, and that although the West is still superior at sea "Soviet fleets are now able to challenge at every level of military or politico-military activity". But it is in the Middle East that the chief economic effects of military build-up are being felt. Israel has planned this year to spend a quarter of its gross national product on defence, or a staggering \$400 for every Israeli citizen. The only other nation which comes close to spending that much is the United States, which reckons to spend \$393 a head this year, while Britain, for example, should spend about \$100. Egypt on the other hand, is planning to spend slightly more in absolute terms than Israel, but this amounts to about 13 per cent of its GNP.

SEAL DEATHS

From Natural Causes

FORTY or so grey seal pups which were found dead or dying on the Cornish coast last autumn were suffering neither from pollution, nor from an epidemic, but from starvation after premature separation from their mothers. The deaths, in other words, were part of the normal juvenile mortality of the local seal population, according to Mr W. N. Bonner of the Seals Research Unit at Lowestoft, who has been conducting an investigation for the Natural Environment Research Council (*NERC publ. series C, no. 1, 1970*). On average some 60 per cent of all pups die in their first year, and this figure is likely to vary widely in stormy weather or crowded conditions, when pups can easily lose their mothers during the crucial three-week suckling period.

In view of the widespread publicity that the deaths received, and the ensuing speculation about pollution which blew up because of the Ministry of Defence experimental establishment at Nancekuke (Cornwall), eleven of the dead seals received post-mortem examinations. In all cases the primary cause of death was malnutrition; four of the seals had complications such as pneumonia or septicaemia, but the rest had simply starved. No startling amounts of contaminant were found in tissue samples, and even though the seals' blubber contained more polychlorinated biphenyls than expected, the concentration was well below that found

Table 1

Table 1. GROWTH OF INTERCONTINENTAL BALLISTIC MISSILE (ICBM) AND SUBMARINE LAUNCHED BALLISTIC MISSILE (SLBM) STRENGTHS 1960-1970.

		1960	1962	1964	1966	1967	1968	1969	1970
USA	ICBM	18	294	834	904	1,054	1,054	1,054	1,054
	SLBM	32	144	416	592	656	656	656	656
USSR	ICBM	35	75	200	300	460	800	1,050	1,300
	SLBM	—	some	120	125	130	130	160	250

in routine analyses of East Anglian seals. As far as the effluent from Nancekuke is concerned, Mr Bonner finds that the standard of treatment is high enough to leave the Ministry of Defence wholly blameless.

Why then did so many seals die last year? One possibility is that the initial publicity encouraged more people than usual to report the dead seals they had seen—in most years there are eight or nine reports of pups in difficulties, but dead seals are usually ignored because nothing can be done for them. Some pups may have been driven to Cornwall from the colonies in Pembrokeshire during periods of strong winds in early November, and bad weather would in any case bring about heavy mortality among the seals which breed on the inhospitable Cornish coast. Extraneous factors thus seem unnecessary for an adequate explanation, and natural causes can also account for lesions seen on the necks of four adult seals at the same time, because seals often fight during the breeding season and receive wounds which can become infected.

Only about sixty to seventy-five pups are born in Cornwall each year, so the mortality rate seems to have been very high indeed. A tour of the breeding localities in December, however, revealed at least six young seals, of which all but one appeared perfectly healthy, and allowing for those which would have been hidden away in caves or other inaccessible parts of the coast a fair survival of pups seems likely.

EDUCATION

Soviet Students Better Prepared

from our Soviet Correspondent

THE new academic year always receives massive coverage in the Soviet press. This year, the last of the current five-year plan, the opening of schools and universities has been even more extensively reported than usual. The implementation of the resolutions of the twenty-third party congress must be discussed and tentative proposals made for the forthcoming twenty-fourth congress.

The expansion of higher education was one of the chief policies of the twenty-third congress. According to the Soviet Minister of Education, Comrade V. P. Elyutin, during the past five years 48 new higher education establishments have been opened in the Soviet Union, including eight universities, fifteen technical-engineering institutes, an institute of electronic technology (in Moscow) and several other specialized institutes and polytechnics. Special emphasis is placed on the training of young specialists for the new professions, such as automation and cybernetics, or in those subjects, such as geology, which have a particular importance in Soviet planning policies.

Recent educational directives and laws have been aimed at providing higher education for young people with a good work record in factory or collective farm, and for ex-servicemen. Special training schools have been established to prepare them for university entrance, and accordingly they are well-represented in the 900,000 new students entering Soviet universities and institutes of higher education. (Of this 900,000, half a million are full time students, and the remainder will be attending part-time and evening courses.) Presumably as a result of the establishing of these training schools, the Minister says that the general educational level of the new students has risen considerably.

FOUNDATIONS

Mr Young's Last Year

THE Nuffield Foundation this week published its last annual report under the directorship of Mr Brian Young, who takes up his appointment next month as Director-General of the Independent Television Authority. Mr Young's departure, after six years with the Nuffield Foundation, comes at the end of a year in which the foundation awarded nearly 100 new research grants worth more than £1.3 million. Most of the grants were awarded in accordance with policies established during the past few years.

In scientific research, for example, the emphasis was on biology—£250,476 was allocated to biological research compared with £16,946 to other scientific research. The foundation defends such a bias on the grounds that "the physical sciences, and technology, are already more lavishly provided for, yet it may well be that the greater needs—not only in terms of money but with the over-all benefit to society in mind—may lie in biology".

Again following the pattern set by previous years, the foundation's educational programme was given the largest share of the foundation's grants in 1969, but attention is now being directed chiefly towards higher education. This in part reflects the success of the Nuffield-sponsored schools curriculum projects during the 1960s, which have led to a change in the nature of the university and college student intake. A grant of £80,000 has been awarded to five universities—Bath, Birmingham, Glasgow, London (Chelsea and Queen Elizabeth Colleges) and Sussex—to collaborate on a project designed to produce new teaching materials for undergraduates in the biological sciences. Two grants were also awarded in 1969 for research in the field of teacher training, one of which is aimed to prepare science teachers for the new types of secondary school curricula—many of them associated with the foundation's own Science Teaching Project.

As far as the social sciences are concerned, the foundation continued last year to back people rather than programmes. For example, Professor A. J. Brown of the University of Leeds was given a grant of £8,250 for work on regional economics, Professor Max Gluckman of the University of Manchester was given a grant to relieve him of the commitments of regular teaching and administration so that he can devote more time to studies of comparative politics and law, and Professor Sir Karl Popper has been given a grant to carry on with his studies after his retirement from the chair of logic and scientific method at the London School of Economics.

Table 1. NUFFIELD FOUNDATION GRANT ALLOCATIONS 1969

	Total allocations	Allocations 1969
Science		
Biological research	2,967,397	250,476
Other scientific research	1,690,624	16,694
Medicine	4,671,890	113,493
Social research	3,562,011	200,516
Education	4,372,137	303,787
Care of aged	2,058,636	115,339
Commonwealth	3,857,393	83,750
Fellowships and scholarships	3,114,075	186,430
Recoverable grants	270,400	32,500
Total	26,564,563	1,303,237

EDUCATION

Computers for the Million

ALL undergraduates, and not just those specializing in the sciences, should be taught how to use computers. This is the conclusion of a joint working party set up by the University Grants Committee and the Computer Board as much as anything because of concern about the widespread lack of awareness of the potential of computers (*Teaching Computing in Universities*, HMSO, 2s 6d). Although their blanket recommendation of programming experience for everybody may cause dismay among arts and social science students, undergraduate scientists will be glad that the inevitable introduction to computing occurs sooner rather than later. Too much time is lost by people having to start from scratch at postgraduate level. The justification for including non-scientists is that graduates from all disciplines take up posts in industry and government, where an understanding of computers is becoming increasingly important. Although it would obviously be preferable if everybody learnt the rudiments of computing at school, the working party, under Professor G. A. Burnard (University of Essex), is working on the principle of better late than never.

At present the chief obstacle to the spread of computer education at undergraduate level is a paper one. The machines supplied by the Computer Board, the chief source of computers for the universities, are limited by the board's terms of reference to use in research only. Several directors of computing laboratories told the working party that they felt unable to increase the amount of teaching because of the board's terms. At the working party's recommendation the government has now agreed to extend the terms of reference to include the supply of computers for teaching. In a foreword to the report Mr Kenneth Berrill, chairman of the UGC, and Professor Brian Flowers, until recently chairman of the Computer Board, say that the extra hardware required between now and 1973 will mean an additional expenditure by the board of only about £1 million, and that a start can still be made on carrying out the working party's recommendations. The report says that a realistic time for the introduction of elementary courses would be the session 1972-73.

Teaching in computing at undergraduate level is at present patchy and thin, the report says, and at some universities non-existent. The report suggests that an introductory course should be run usually in a student's first year, preferably with the students having direct access to a computer through on-line consoles, although the report recognizes that, to begin with, most universities will have to settle for indirect access using card or paper tape inputs. This will mean developing compilers that allow a computer to handle a batch of simple programs that might be produced by a class of students more quickly than if the computer went through the normal operating procedure with each separate program.

It would be best, the report says, if the elementary courses were not taught by the staff of each university's computer laboratory but by the staff of the students' department. Departmental staff will be better able to stimulate the students with relevant applications of computing, but demonstrators should help the students with their programs.

ART COLLEGES

Art without Design

THE general malaise of art education, which has only been brought to public attention by the bitter and protracted disputes at Hornsey and Guildford colleges, is unlikely to be greatly alleviated by the long awaited report of the Coldstream Committee. The committee, under the chairmanship of Sir William Coldstream, has been looking into the whole structure of education in art and design, and it has published its recommendations this week (*The Structure of Art and Design Education*, HMSO, 7s).

The committee suggests, but without much discussion of the rationale behind the suggestion, that the present Diploma in Art and Design (Dip AD) should be substantially modified. Some of the design courses should be taught separately as four-year sandwich courses, with up to one year spent in industry, while the remaining courses should be flexibly grouped into four chief studies—fine art, graphic design, three-dimensional design and textiles/fashion. The committee lays considerable emphasis on the flexibility of the groupings, and suggests that students should be able to pursue a broader range of studies which cross or overlap the boundaries of the groupings. The sandwich courses, on the other hand, should have a "substantial specialized technological content which can best be studied in close association with the relevant industry or profession". Students should be able to transfer from the sandwich course to the Dip AD or vice versa only in exceptional circumstances.

The committee also suggests that students should be able to enter the sandwich courses after a good general education of sixth form standard, while those wishing to take the three-year Dip AD course must still take the one-year foundation course except in special circumstances. But the most grave and pressing problem at present facing the potential art student is that many more students leave the foundation courses in search of a diploma course than the diploma colleges can accommodate. It is this huge demand for places that creates much of the frustration and discontent in art education. What the committee proposes is essentially that the number of places in foundation courses should be limited: "some form of central control of foundation courses is necessary so that the number of people being prepared for diploma courses and the number of diploma places available relate more closely to each other", and so the bottleneck will be shifted but not removed.

How does the development of the polytechnics, and the general expansion of further education affect the committee's recommendations? Unfortunately, the recommendations seem to have been made without much regard to—or at least without much discussion of—the rest of the education sector. To be sure, the report points out that there are some considerations which have not been included because the committee was anxious that its recommendations should be made as soon as possible, but a discussion of the part to be played by the art colleges in the polytechnics and some consideration of the interactions between art colleges and, for example, colleges of education seems a striking omission.

British Association

Who is Responsible?

from our Special Correspondent

Durham, September 8

THE luckless British Association, assailed as it is by financial troubles from within, is now being sued by two members of the British Society for Social Responsibility in Science on the grounds that the secretary, Dr Henry Turner, earlier this year circulated within his organization a statement announcing the intention of the BSSRS to intervene at this year's meeting at Durham in terms which, it is alleged, were defamatory of some members of the society. Earlier this week, the parties alleging injury also put out a statement protesting that the "hierarchy" of the British Association has been unresponsive to the real questions of the day and, for practical purposes, giving up the British Association as an organization beyond redemption.

The activities of the BSSRS—represented here by research students for the most part—have been diligent, amusing but often beside the point. Their activities began at the end of the opening ceremony last week, when several people enacted the perils of nerve gases. There has also been a stream of pamphlets and broadsheets denouncing the supposed irresponsibility of the British Association. Many members of the association were also present at the teach-in last Saturday, when the question for debate was the neutrality (or otherwise) of science.

The most constant reminder of the presence of the BSSRS has been the stream of interventions at the formal proceedings of the sections of which the British Association is composed and—fair play—most of these have been polite if not articulate. But many well-wishers must have been downcast at the factual inaccuracies with which the attacks on what is called the Establishment are larded. (One of the more tricky questions for the students—apparently unanswered—has been posed by the way in which Professor John Ziman, the president of the General Section, has consistently sported a button with the letters SRS for "Social Responsibility in Science".)

The organizers of the meeting, many of whom clearly appreciate the problems that the BSSRS is worried about, may have felt pangs of indignation, for some sections seem to have made an effort to bring social and environmental questions to the fore. Those devoted to sociological and general topics led the way by spending a day discussing the sociology of science. And the botanists, perhaps still smarting under last year's jibes that their subject is dying or dead, heard their president, Professor P. F. Wareing, speculating on how they could help to increase the world's production of food. The geography section devoted a morning to discussion of

population and development in the Middle East and another to the problem of derelict land. Durham, with its 16,000 acres of officially derelict land, is a fitting place for such a discussion, especially in view of the good work done already in reclaiming much of it (page 1082).

The environment, as might have been expected in European Conservation Year, received plenty of attention. Apart from an exhibition on water resources, and various individual contributions throughout the week, four sections, comprising biologists and geographers, combined to mount a large scale symposium concerned with conservation and productivity. For this, speakers from the Nature Conservancy turned out in force.

There was perhaps some justification for the impatience of the SRS group with the general reluctance to discuss political aspects of pollution, population and so on. Much of what was said about the need for conserving wildlife and fisheries seemed to have been heard more than once before. A broader discussion might not have proved too much for BA members, many of whom must be convinced conservationists in any case.

Putting man first, the sociologists spent a morning discussing public participation in planning, and an exhibition called Phoenix '70 illustrated public and private contributions to the social and economic development of the North-East of England. One of the more interesting of a generally uninspiring handful of displays was provided by Durham Constabulary and the local Home Office forensic science laboratory. It is good to know that X-ray crystallography, infrared photography, differential hologram interferometry and emission spectrography have useful applications in the apprehension of criminals. The police were also the subject of a morning's session opened by Professor M. Banton with his presidential address to the sociology section. Medicine was the topic for dissection during a general symposium on new doctors' dilemmas. Dr Henry Miller chaired a day of deliberations on transplantation, treatment of mental and physical abnormality and the misuse of drugs.

Clearly the BA is open to criticism for not giving more prominence to questions of social responsibility, but equally it is unfair to condemn it wholeheartedly, as this year's proceedings have shown. A worthwhile enterprise for the future might be a large scale symposium devoted to the topics that the SRS group were raising at Durham—warfare, the politics of pollution and so on. That at least should not prove too embarrassing.

DEVELOPMENT

Science makes Development Sweet

from our Special Correspondent

A CHEERFUL account of the ways in which scientific institutions are being set up in developing societies was provided at a symposium earlier this week at the British Association's annual meeting at Durham. One striking feature of the proceedings was the forthright rejection of the view that the technology of advanced societies might serve only to corrupt the developing nations by Professor T. Adisanya Ige Grillo, professor of anatomy at Ibadan, Nigeria. The button-wearing doomsdayers seemed for a time abashed to discover that a Nigerian could be as keen on technology as any go-ahead industrialist.

The symposium, organized by Professor John Ziman as part of the proceedings of Section X (for General), was conducted by Lord Blackett, president of the Royal Society and a distinguished recruiter of science in the cause of economic development. The difference between the two categories, he said, is most easily measured by per capita income—\$600 per head on the average for the developed nations and only about \$100 per head for the developing nations. But there has been progress. The developing nations have collectively increased their economic wealth by about 5 per cent a year in the past decade. Yet economic progress remains the goal, and so every scientist must be imbued with the notion that social progress in the developing world must be the goal only next in importance to the avoidance of a nuclear war.

The case for variations of the conventional pattern of science teaching in the developing countries was put by Professor D. G. Osborne of University College, Dar es Salaam. Science graduates, like members of the general population, must be "competent for change", he argued, and must be trained for making administrative decisions with a scientific content as much as for research or even teaching, which argues the need for mixed courses—economics and physics, for example. He asked that textbooks written for students in developing nations should be more fully provided with illustrations relevant to the societies concerned, that more graduates from universities in developing nations should be able to have postgraduate training in other countries and he pushed for innovations such as a scheme to induce developing universities to spawn from within themselves industries suited to regional needs. Among the impediments to scientific education in developing nations are the lack of the kind of general awareness of scientific matters that might be provided by newspapers or other non-professional journals, the linguistic background of the students (not usually English) and cultural restrictions such as the tendency to believe that a person should not dirty his hands.

Dr H. C. Pereira, director of the East Malling Research Station, slew two paper tigers with his declaration that the unwillingness of farmers in the tropics quickly to change their methods has at least the advantage that new crops disastrously susceptible to new diseases are not introduced, and that the merchant banks which operate on the fringes of the cash economy do worthy service for tropical agriculture. Dr Pereira argued strongly for "science on the spot" if practical problems were to be dealt with efficiently.

Nigerians do not easily forget the civil war, only recently at an end, and Professor Grillo several times returned to his statement that the troubles had at least helped Nigeria to recognize its own internal strength. He was scornful in an amusing way about past attempts at aid for developing countries—"you cannot help people without knowing what they want" was one of his themes. He pleaded for "a certain amount of faith" in the capacity of African scientists, however trained, to know what they were about, and claimed that the development of educational institutions in Nigeria at least had now reached the point at which "we are no longer in a position to put the blame on the colonial past . . . if there are mistakes, they are our mistakes". But he thinks it unlikely that Nigeria will ever again establish classical universities—technical institutions are the pattern.

Professor Grillo welcomed the notion that there should be easy exchanges of people between developed countries and Nigeria, but had a sombre warning for the developed nations and especially for Britain about the quality of the people sent to the developing nations as university teachers. With all the links now extant with developed nations, these universities had become places where the developing peoples could make international comparisons and in which the third-rate people were conspicuous.

The development of health services in Nigeria is a centrepiece of the strategy of the National Science Council of Nigeria, and Professor Grillo promised that Nigeria would have a more carefully planned programme of medical research than any in the United States or Britain. He was scornful of the way in which the National Institutes of Health in the United States were persuaded to start a programme of congenital lung diseases in the newborn after the death of one of Mrs Jacqueline Kennedy's children, anxious to say that malnutrition and disease are often just as much consequences of ignorance as of poverty, and yet convinced that health engineering as he called it—the prophylactic management of the environment—is often more important than mere doctoring, nevertheless, Professor Grillo said, Nigeria would in the development of medical schools make sure that intending doctors received a good grounding in the medical sciences.

To many of his audience, Professor Grillo's most surprising declaration was that there is at present no reason why Nigerians should without further thought accept the advice of outsiders that the time has come urgently to reduce the rate of growth of the population. "Is there a population problem in Africa? We doubt it. And all this anxiety about family planning—is it genuine? That's what we have to decide." He went on to quote as evidence in favour of doubt the ease with which "you can get the money for an electron microscope from the aid organizations so long as you say it's for family planning".

The civil war apart, Nigeria (with oil) is luckier than most developing countries. What Professor Grillo had to say reflected also a sense of cheerfulness which seems—at least to judge from the inevitable questions of the students at the back—to be vanishing in the developed world. At one point he was almost on the point of saying that the women's lib would have nothing to ask for in Nigeria, but this statement eventually appeared as "the women of West Nigeria play a very important role".

LAND RECLAMATION

Spoil Heaps into Pastures

from our Special Correspondent

THE hated spoil heaps of Durham are disappearing under a lush growth of grass and trees. The mountains of black shale which remained after the closure of the county's many coal mines are being flattened and planted to convert them to pasture, woodland and recreational areas which defy recognition as the eyesores of the past. Last week some of the pioneering work carried out in Durham gladdened the hearts of members of the British Association. About twenty of them were conducted on a fifty mile tour of about a dozen heaps, reclaimed and being reclaimed, by Dr A. J. Richardson of the Department of Botany, University of Newcastle upon Tyne, and Mr R. Briggs, Durham County Council's Landscape Reclamation Officer.

One of the oldest examples was a small wooded hill which had been a spoil heap planted with trees in 1927 by the county council. In spite of this early start in reclaiming derelict land—long before concern for the environment reached its present status—the council did not swing fully into action until after 1950. Between 1954 and 1960, however, about thirty small heaps were tackled, representing about 700 acres of reclaimed land. After the Local Employment Act of 1960 made government grants available for reclamation (50 per cent of the cost, increased to 85 per cent in 1963), the council set up its reclamation unit. Then it really got to work on the 350,000,000 tons of pit waste deposited in the county during the past 200 years.

The largest scheme so far is in progress near Thinford, where 2.6 million out of 7 million cubic yards of spoil is being spread onto adjacent agricultural land, which, as in many cases, has been purchased by the council. Work began last February, and grass should be growing by the summer of 1971, at an estimated cost of about £278,000.

Another scheme at nearby Sherburn Hill has involved a reduction of nearly 130 feet in an ungainly 200-foot conical heap, which has been merged into an adjacent limestone ridge. Available topsoil is being spread over the new surface ready for seeding with grass. The reclaimed land will be used for grazing, and some trees will be planted. This is costing £105,000. About twelve miles away are forty-five acres of pasture, woodland and open space which were once a 190-foot high spoil heap dominating the town of Willington. Reclamation began with the shifting of about 15 million cubic yard of material in October 1967, and, within a year, grass was growing on the reshaped mound, some of it sown on top soil and some put directly into the shale.

At Reddymoor Colliery, near the town of Crook, the spoil heap is now covered with the grasses *Agrostis tenuis*, *Dactylis glomerata*, *Festuca rubra* and *Festuca ovina*. This heap is part of the University of Newcastle upon Tyne's landscape reclamation project, and various trees and shrubs are being tested for their suitability to such conditions. *Sorbus aucuparia*, the rowan tree, is doing quite well and so is *Rosa rubiginosa*, sweet briar, but *Robinia pseudacacia*, acacia, is not, nor is *Sambucus*, elderberry. Acidity and lack of nitrogen often have to be overcome by a judicious use of lime and fertilizer.

Brancepeth pit heap as it used to dominate Willington (top), and as it is now (bottom) after treatment by Durham County Council.

NEW WORLD

Intellectuals of the World Disunite

by John Maddox

Aspen, Colorado, September 4

ON the face of things, this remote almost alpine valley is either the least appropriate or the most suitable place in which to hold a conference about the relationship between technology and the rest of society. If the problem is the pollution of the environment, the splendid mountains are a sign of how good things can be and the ski-runs a proof that people want not wilderness but blissful recreation. If the issue is economic development, then Aspen is also a good setting, for there are already signs of what the village will be like when great ski lodges have been grafted to the Victorian frontier resort of just a few years ago. Yet in the event, the setting turned out to be unsuitable for the conference on "Technology—social goals and cultural options", organized jointly by the Aspen Institute for Humanistic Studies and the International Association for Cultural Freedom. The proceedings seemed to begin well enough, but in the end the hundred or so participants had little to say except that they had no single view about the place of technology in the modern world. Worse still, this disagreement was conspicuously etched out, for the benefit of local residents and the international press, at a meeting yesterday that will surely be remembered as long as conferences are held as an example of how the nicest and the cleverest people (but perhaps *they* stayed away) can do each other mischief in public. Is the altitude (8,000 feet) responsible? Or the reputation of this valley for being grand? Or is it the simple truth that there can be no simple statement about the relationship of technology and the big wide world?

No report of these confused proceedings, sometimes byzantine but also sometimes uplifting, can be objective, so that many other participants will have their own versions of what follows. It is, however, a fact that none of the seventy people present dissented from the proposition that there is something to discuss. The proceedings opened with statements of the need to know how to live with technology from Mr R. O. Anderson, chairman of the Aspen Institute (who is also an Atlantic-Richfield oil man and on that account especially concerned about (a) pollution and (b) natural resources) and Mr Joseph Slater, President of the Aspen Institute and also of the Salk Institute over the next row of mountains to the west. On reflexion, it was probably a mistake to begin with what was billed as a dialogue between the co-chairmen of the meeting, Dr Alexander King (OECD, Paris) and Professor M. Gell-Man (California Institute of Technology). There is a limit to the number of times on which people can say to each other in public "Well, Murray", or "Well, Alex" and still retain a serious demeanour, at least if they are not professional actors. One curious effect of this format was to create an impression of alarm among the audience which the speakers themselves say they had not intended. Is

there a crisis, and is it a crisis of the environment? Some thought not, and thought that the actors had gone beyond the bounds of reason. Others thought yes, but thought the actors had been too mealy-mouthed. What did they really mean to say? This uncertainty, neither a conviction of doom nor cheerful optimism, seems to have cast its spell over the three days that followed. In circumstances like these, it is only fair to say that some useful work was done. Closer knowledge rather than deliberate choice means that there is more to say about the group of people worrying about "problems of economic and demographic growth". The chairman, Professor Roger Revelle, the oceanographer turned demographer who is the director of the Harvard Center for Population Studies, is a mine of information about natural resources, fertility rites the world over and even carbon dioxide in the atmosphere. He ran a comparatively optimistic group of people through a short and narrow course in which numbers and principles were mixed more or less to suit all tastes. What were the results?

First, actual food supply is not a limitation for the world's population—the earth could support 50,000 million people if only existing agricultural techniques were applied most efficiently to all cultivable land. Moreover, there are already signs that the birth-rate is beginning to decline in those small developing countries where the pace of economic development is greatest. But Singapore, Hong Kong, Taiwan, Jamaica and even Albania seem to have paved the way for falling birthrates to follow elsewhere once economic development gets under way. The moral, everybody in the group agrees, is to encourage economic development not merely for its own sake but also as a means of bringing population to a stable level. People hope that if all goes well, the population of the world might settle down at 15,000 million a century or so from now.

Why bother? Is the danger the lack of resources? Quickly it turns out that fears on this score are even less serious than the danger that food will be hard to grow for a population of 15,000 million, even if there will have to be a great deal of substitution (such as aluminium for copper or uranium for oil). At least from this comfortable distance, the chief reason for hoping that populations will not grow too quickly is that there is bound to be a trade-off between the rate of growth of a population and the rate at which it can improve its economic and social lot. Neo-colonialist though this sentiment may seem in other circumstances, nobody raised a voice in protest.

But what about the danger of spectacular disasters? Carbon dioxide and the greenhouse effect is at the top of every doomsday list. By all accounts, there has recently been a solemn study of the likely accumulation of carbon dioxide in the atmosphere from the burning of fossil fuel, and it turns out that the exhaustion of the world's reserves of fossil fuel would increase the

carbon dioxide content of the atmosphere by 25 per cent and the temperature at the surface of the Earth by about 3 degrees Fahrenheit (which is, of course, enough to make climatologists lie awake at night). But then everybody agrees that what matters is the rate at which carbon dioxide is released into the atmosphere, and that a moratorium on the burning of fossil fuel would mean that the concentration would depend on the balance between the oceans (which are a sink for carbon dioxide) and the release of gas from volcanoes and the weathering of rocks, with the biosphere holding the balance in between. In short, stop burning fuel and the carbon dioxide will be what it has been for most of the past 10,000 years at least. Everybody heaves a sigh of relief.

Resources, however, are only half the problem. What about capital and foreign aid? This is where the gloom begins. Will the United States ever again be able to increase the amount of money spent on helping economic development elsewhere? Or will Western Europe have the will to take up the fallen mantle? Nobody can tell, but one African participant does vigorously affirm that there is no point in merely building an aluminium smelter alongside the Volta dam if it only uses local resources (in the form of hydroelectric power) and not even local bauxite and does not contribute to the skills of Ghana. Liberal men and women from all over the world agree that aid-giving countries must lean over backwards to allow developing nations to find their own way forward, that organizations such as the World Bank should be even more willing than at present to allow social benefit as well as financial profit to be a consideration in making loans and that it rings hollow for developed nations to urge on developing nations the attractions of international trade only to erect tariff barriers to keep out foreign goods whenever domestic industries are threatened. Developed nations, in short, should settle for more advanced forms of technology.

But what of the developed nations? These, after all, are the lands in which the SST will fly. To begin with, there is great favour for the belief that avoiding nuclear warfare is the first objective. From the group with Mr Harvey Brooks as chairman and from others, there is also great enthusiasm for the practice of what Mr Brooks himself has called technological assessment, as well as for the somewhat more nebulous "techniques of intervention in technological development and deployment by control, regulation, or the provision of positive or negative incentives in a manner sufficiently flexible so as not to inhibit or discourage beneficial innovation." In short, if the SST is a nuisance, tax it. This group, like that brooding on developing countries, is destined to feel the sharp edge of Miss Mary McCarthy's tongue—Panglossians, optimists and relativists to a man, she calls them.

Other groups have less cheerful conclusions to report. Those concerned about the ways in which technological developments could be controlled consider that affluent communities and societies make the pace—the poor and disadvantaged cannot afford such doubts. To what extent does this stem from some sense of exclusion from the decision-making process? And is there a danger that the making of decisions on technical matters will come to be divorced from the political process? People are against "creeping back-room technology" as one person calls it, although

nobody goes as far as to fix this label on Mr Brooks's technological assessment. So people went on to ask for better regulatory institutions and to assert that there is nothing wrong with parliamentary democracy that participation could not cure.

Educational institutions are a splendid case, and Dr Ivan Illich, philosopher and one-time Jesuit from Mexico, startled everybody with tales of how many of the communities in South America could afford neither the practice of classical education nor the social straitjackets which it makes. Why not, instead, some mixture of apprenticeship, skill training and motivated literacy training, for is not the classical system (as followed in the United States) an invention of the middle class? Indeed, is not even childhood such an artefact? Everybody wonders about this, hoping only that Dr Illich will find some way of making sure that people can escape from their environments if they wish.

With hindsight, no doubt, the organizers are probably convinced it was a pity not to have brought these opposing views together, but none of that explains why the conference should finally fall flat on its face in an attempt to hammer out a statement. For are not respectable differences of opinion tolerable or even enlightening? A part of the trouble seems to have been the belief that the circumstances called for a manifesto, not a summary of the proceedings. Another is the

MEN have from the beginning used technology to alter the physical and social environment. One should not underestimate that accomplishment. Technology has eliminated hunger and misery in many countries, and it can do so in many more. It has helped to halt malaria, polio, famines, and floods. It has provided unprecedented opportunities for education and for the development of individuality.

Yet technology has also served the interests of suppression, genocide, saturation bombings, and economic exploitation. In other words, technology can become the tool of mindless, selfish, or malign governments or industries that overlook human ends. Today, moreover, technologies are so powerful that they can threaten radical and irreversible changes in the entire planet, in the quality of human life, and even in the biological nature of man. The root of the problem is not in technology as such, but in its generation, its management, its use, and in the difficulty of controlling it.

We are concerned both about the sense of defeat shown by many young people and poor people and about the complacency of large sections of the public in all countries. We are also concerned about the continuing deterioration of many parts of our natural environment.

We are all agreed that the problems of poverty and human deprivation are the most pressing we now face, but we are also unanimous in the belief that there will be an environmental crisis if we do not take deliberate and timely steps to prevent it. —extracts from a statement adopted by the majority at the conference.

strange zeal with which one of the chairmen, Professor Murray Gell-Man, is forever sponsoring alternative draft documents to whatever the rest of the conference has agreed to commission. The first collision between an official draft and one tucked away in Professor Gell-Man's sleeve is the commissioning of yet a third, which is in turn capped by an armful of Xerox copies from Professor Gell-Man, rich with mindless phrases such as "mindless, selfish or malign governments". In the end, those not driven into the sun by the rephrasing of the sentences find themselves agreeing that the statement as finally issued should even make obeisance to the women's liberation, but in the small hours and the umpteenth redrafting, this laudable sentiment is left out. Is there something about typewriters that can spot irrelevancy when people are exhausted? Will there ever again be such a splendid chance for finding out?

TERRORISM

Bombing at Madison

from a Correspondent

ON August 24, just three weeks before the fall academic session was about to begin at the University of Wisconsin, Madison, terrorists blew up the Mathematics Research Center. One graduate student was killed, four persons (including a graduate student from South Africa) were injured and \$6,000,000 in damage was caused. The bombing capped a 19-month period in which the National Guard had been called up three times—twice for campus disruptions and once to guard the nearby capital of the state of Wisconsin. Madison, a city of 170,000, once was called by *Life* magazine the best place in America to live and study. The then picturesque, tranquil campus of one of the nation's leading public universities was cited as an asset in that article more than two decades ago. Tension is high and optimism is low in Madison these days. There are doubts whether the university will be able to complete its fall semester without serious incident. Students are reported to be stockpiling weapons; and a rather large "hippie colony" has made the city its home, much to the concern of the city's establishment.

The bombing took place at 3.40 am. At about midnight, a nuclear physicist, Robert Fassnacht, 33 years old, had gone to work to finish up some research before a scheduled vacation with his wife and three children. His body was found beneath the rubble. Data books of five postdoctoral colleagues were also buried, and their loss has in some cases set back the students by as much as three years. The physical sciences community across the nation was shocked by Fassnacht's death. Until now, by and large, social scientists and humanists have been those mainly involved in, and affected by, the student revolt. It is the scientists who have now been provided with dramatic evidence that they are not immune from the capricious terrorism of youths bent on destruction of research centres.

Later, a militant radical group called the New Year's Gang spread the word, through an underground newspaper story, that they did the bombing. Four young men, three of them school drop-outs and the fourth a former editor of the student newspapers have been charged with the bombing by the FBI.

Demonstrators on campus streets insisted that the

bombing was done only after a year of other protests had been futile; that the research centre did work directly on projects related to the Indo-China war, that the bombing had been a humane act—designed to save lives of Vietnamese, Cambodians, Laotians and American soldiers. Ironically, many of the researchers who worked in the demolished Sterling Hall also were "doves" but they did not believe in terrorism. The New Year's Gang has threatened that, if its demands are not met by October 30, 1970, there will be kidnapping of public officials in the Latin American style. Its demands include abolition of the Army Reserve Officer Training Corps centre on the Madison campus as well as the "elimination of the male supremacist women's hours at the university."

Sterling Hall was and is the University of Wisconsin's main physics building. The basement and first floor house the school's physics experiments and these were most heavily damaged. As part of the physics department, there is a 10 MeV accelerator financed by the US Atomic Energy Commission. The second, third and fourth floors are used by the Army Math Research Center though the third floor is shared by the university's multi-million dollar computer centre. Floors five and six house the university's astronomy department.

The biological sciences also were affected by the bombing. The School of Pharmacy building is located across the street from Sterling Hall. Dean David Perlman estimated that about \$1,000,000 in damage had been done to the pharmacy building. "One cannot equate in dollars and cents the loss suffered in the areas of cancer, Parkinson's disease, antibiotics, and many other facets of pharmaceutical research lost due to the bombing," he said.

Sterling Hall Physics Building.

The Mathematics Research Center was established about 15 years ago with financial support provided by the United States Army. Its mission was to do basic research in applied mathematics. Wisconsin was one of several universities that had placed a bid to have the centre located on its campus. The centre has been host to mathematicians from many countries of the world, including Yugoslavia and Egypt. Under the centre's arrangement with the US Army, support is given to foreign scientists who could not otherwise obtain funds from even such US research agencies as the National Science Foundation. All of the work at the centre is

unclassified, and available to all who ask or pay the purchase price of books or research papers in which results are published. Professor J. Barkley Rosser, director of the centre, says that "none of the work is in any sense secret. The problems on which we work are basic and usually pertinent to many fields of science".

For several years, the Army Math Center at Madison has been the target of picketing and sit-ins by young radicals, some of them students at the university, others just gypsy-like dissenters who wander across the nation looking for causes, usually identified as anti-war crusades.

On February 12, 1970, students broke windows in the Math Center during demonstrations against the General Electric Co., which had sought personnel recruits on the campus. The student dissidents accused GE of being a major defence contractor. Windows were broken in the centre a week later as a protest at the outcome of the Chicago 7 conspiracy trial. Last April 18, when President Nixon ordered the invasion of Cambodia, the building was attacked again. Thus, within a month, a building that had relative peace for nearly 12 years—it was built three years after the Math Center was established—became a target for student dissent. Rosser, who likens the centre to a "think tank", says that the centre received more than \$1,000,000 in support from the Army last year.

Aware of the negative image of the Math Center on the campus, a 32-page detailed explanation of its work was sent to all members of the Wisconsin faculty last fall. The booklet described activities such as the centre's mathematical studies of what happens when a hole is punched in a sheet of metal or plastic. The centre has also undertaken studies of the properties of elastic substances, and the mathematics of wave action.

COMPUTERS

Living with Machines

from our New York Correspondent

A COMPUTER conference "committed to the proper management of computer technology for the greater good of mankind" was held last week in New York City. The 25th national conference of the Association for Computer Machinery stressed that scientists care about society and attempted to create dialogues between computer experts and computer users. At times the dialogue dissolved into competing monologues, but the will was there, and hopefully the way will follow.

The first day of the conference considered the application of computers to urban problems. Marvin L. Mannheim, a civil engineer at the Massachusetts Institute of Technology, delineated what he called the "myth of rationality", the belief that there is a single best course of action and that the computer can determine it. There can be no such thing, he said, since any definition of what is best is determined by values that differ for every group. Value discussions are hidden in everything we do, Dr Mannheim added, and since it is far more difficult to define the qualitative values than the quantitative, the latter are usually emphasized though the former are probably more important. Even when a programme attempts to assign numbers to social and aesthetic functions, it proves to be an almost impossible task.

David Grossman, the Deputy Director of the Budget for the City of New York, argued that the political process is already closely allied to decision-making but often there is too little guidance of any sort, so that what is really needed are measurements that could be looked at with a cold eye. Dr Mannheim agreed that this was one of the potential benefits of computer use in this field and narrowed his attack to those limited studies that only focus on parts of a problem in the belief that a computer can provide the total information necessary for reaching a decision. He felt that all a computer could attempt to do was fill in the blanks in the statement, "these are the key courses of action that could be taken, with these interest groups gaining and these losing."

Urban hardware was the theme of John P. Eberhard, Dean of the School of Architecture and Environmental Design at Buffalo. "The second generation of urban hardware now around us has replaced the first generation that was in operation for thousands of years," he said, "but all of the necessary components—steel, elevators, central heating, indoor plumbing, electricity, the automobile, and the telephone—were developed between 1880 and 1892." We are now in the process of a shift from this second generation to a third, and the old generation must eventually die. The computer industry must be prepared for the challenge of this third generation and must address itself to the problem of being a part of it.

An address by Ralph Nader, the consumer advocate, broadened this appeal to include all problems outside the realm of normal market forces, and brought him a standing ovation from the audience. He called for an information "Bill of Rights" to ensure that the efficiency of the computer's ability to gather and store information does not outpace the development of legal controls preserving society's right to privacy. He warned that if this does not come about soon there will be mass antipathy to the whole technology; "never underestimate the power of the citizen backlash to something it doesn't understand and feels is taking unfair advantage."

The legal question regarding privacy will soon become a major issue, Mr Nader predicted, because it must determine to what extent it is necessary to maintain barriers around people's lives in order to keep society functioning. Legal issues also arise in the area of monopoly power in the computer industry, for there is a danger that when new technology is dumped into an existing corporate structure, an archaic corporation may well block its own use of new advances and at the same time stop new companies from using these advances in dynamic ways. As computers are given increasingly complex tasks in this very interdependent society, they must be able to correct themselves and try new approaches if the entire system is not to be "gummed up", he said. "With such a complex technology, the professional societies must be the first to determine if adequate safeguards are being taken". Mr Nader also noted that "We are entering a period where we can almost program innovation, but the question is, are we going to apply this innovation to those areas that most need it?". Professional standards must provide criteria for choosing between professional, corporate, and personal disputes. "When a professional society allows its standards to atrophy, is the atrophy of the profession itself far behind?"

NEWS AND VIEWS

Crystallographers' Progress

Now that the first shining successes of protein crystallography, lauded in song and story, have passed into history, the applause that greets the unveiling of each new model of a hydrolytic enzyme is becoming a trifle perfunctory. To stimulate the jaded intellectual palate something more overtly spectacular is evidently needed, and on p. 1098 of this issue of *Nature* we are happy to present just such a confection. Rossmann and his team have achieved a 2.8 Å map of no less an enzyme than lactate dehydrogenase, which has a molecular weight of 140,000, with more than three hundred residues in each of the four subunits. The reader, contemplating the stereograms with sagging jaw, might wish to be reminded that NAD is a cofactor for this enzyme, and that it binds independently to one site on each subunit. The high-resolution structure that Adams *et al.* now present is that of the apoenzyme.

The subunits have a compact form, with a cleft down the middle, containing the binding site for the adenylate function of the NAD, which, as recent work by McPherson from the same laboratory has shown, acts as a conformational trigger: its attachment engenders a structural transition to a state with high affinity for the nicotinamide end of the cofactor. The dodecapeptide that has been snipped out of the protein and contains the enzymically active thiol group has been identified, and lines one wall of the cleft. About a quarter of the residues are distributed between eight α -helical segments, and for connoisseurs of polypeptide structure there are some fragments of the rare and desirable 310-helix; 10–15 per cent of the residues are also in the β -form, some in the antiparallel, and some in the parallel form, which has never been found in isolation (as in fibrous proteins), but has been observed in the subtilisin molecule by Kraut and his co-workers. Most of the recognizable secondary structure occurs in the N-terminal half of the chain. Side-chains which are in a position to make contact with the cofactor have been tentatively identified, and Adams *et al.* note that some residues known to be functionally important in another dehydrogenase enzyme, glyceraldehyde 3'-phosphate dehydrogenase, occupy similar positions in the sequence to some that cluster round the cleft in the lactate dehydrogenase subunits. On this basis one might hazard the surmise that the stereochemistry of the active site could well be similar in the two species.

The real pay-off from this work, of course, lies in the future, when the holoenzyme and its inhibitor complexes are also solved at atomic resolution, so as to allow a detailed comparison. From the available data at 5 Å, the general form of the conformational convolution that accompanies the binding of the cofactor has already been defined (Adams *et al.*, *J. Mol. Biol.*, **51**, 31; 1970). In their new report in this issue, the authors

also describe the important step of crystallizing an abortive complex of the holoenzyme with the substrate, pyruvate. From the results at 5 Å, it is already clear that the introduction of the latter brings about a considerable displacement in one part of the molecule—a loop of twenty-four residues making up the mouth of the cleft. This migrates 12 Å, thereby closing the cleft so as to occlude the nicotinamide ring. A change in electron density also occurs in the vicinity of asn-150 and ser-147, which form part of the fragment containing the essential thiol group. Enzymologists will wish Rossmann and his colleagues a swift ascent to the next daunting peak.

PROTEINS

Independence and Togetherness

from our Molecular Biology Correspondent

THE problem of cooperative binding phenomena in proteins, which not so long ago seemed on the verge of illumination in terms of a number of simple generalities, has now, alas, receded once more into a malodorous miasma of complex and contradictory observations. Even the archetype, haemoglobin, which has probably claimed more man-years of research than any other protein, has not been spared. A fresh attempt to impose a simple formalism on the kinetics and equilibrium of the oxygenation reaction has now been made by Gibson (*J. Biol. Chem.*, **245**, 3285; 1970). He has expressed the uptake of oxygen by the four haems in terms of four independent consecutive steps. The data, in other words, must be accommodated by eight rate-constants, four each for the forward and reverse reactions. Now in terms of the varyingly attributed quip that with four independent parameters one can draw an elephant, this seems at first sight a dispensable exercise. But, on closer inspection, a number of restraints reveal themselves. In the first place, the rate constants for the reaction of the fourth oxygen can be independently determined from measurements of the kinetics of replacement of oxygen by carbon monoxide, the carbon monoxide system being kinetically defined by the early work of Roughton and Gibson. The remaining six rate constants must then be selected so as to satisfy a family of curves for the binding and dissociation of oxygen at different levels of saturation. The ratios of the on and off-rate constants must, moreover, be such as to yield binding constants which will fit the equilibrium curve.

These requirements between them are sufficiently restrictive that a set of what one may hope are unique rate constants can be computed. Gibson concedes that he has defined the system only in operational terms, and that more states than the five which are implicit in this scheme must be presumed to exist. It is, however, seen that the cooperative binding of oxygen can be accounted for by the different values of the rate constants. Moreover, their relative magni-

tudes, which imply, for example, a large affinity change after loss of one oxygen, are not readily compatible with a two-state, or allosteric, model which, as this and other evidence indicates, is unlikely to apply to haemoglobin. Moreover, the kinetic basis of the important effect of phosphates, in particular, 2,3-diphosphoglycerate, on the oxygen uptake curve has been determined: the velocity of dissociation of the first oxygen is unaffected, but the other three rate constants for dissociation are greatly diminished when the cofactor is excluded.

A strange case of cooperativity, albeit of a rather low order, occurs in the haemoglobin of the lamprey, which in the liganded form in dilute solution is a monomer, but associates when deoxygenated. Rumen and Chance (*Biochim. Biophys. Acta*, **207**, 404; 1970) have now examined the reaction of this protein with carbon monoxide in the crystal, where it is in the associated state both in the presence and absence of ligands. The experiment is possible because, unlike mammalian haemoglobins, the lamprey pigment has the same crystal symmetry in all states, so that the crystals do not break up on withdrawal of the ligand. An indubitable cooperativity is observed, and Rumen and Chance infer that the haem-haem interactions are not in this case mediated by a relative displacement of subunits within the tetramer as in horse haemoglobin, for example, for otherwise, they reason, the crystal habit would be expected to change. Neither could one envisage subunit exchange processes in the crystal. Just what degree of structural change a lattice can tolerate is a matter of speculation, however, but it is altogether possible that a quite different mechanism of haem-haem interaction might operate in the crystal from that in solution in lamprey or mammalian haemoglobins.

An extraordinary enzyme, in which the cooperativity of ligand binding can be controlled by the presence or absence of potassium ions, is aspartate-homoserine dehydrogenase of *E. coli*, which has been studied by G. N. Cohen and his collaborators. Several conformational manifestations of ligand binding have been recognized, and now Heck and Truffa-Bachi (*Biochemistry*, **9**, 2776; 1970) have made some interesting observations, using circular dichroism as a conformational indicator. Binding experiments with aspartate and the inhibitor, threonine, show that when potassium is absent and there is no cooperative effect, there are only trifling changes in circular dichroism, which are confined to the aromatic region of the spectrum. With cooperative binding in the presence of potassium, on the other hand, some quite sizable conformational effects are observed, the ellipticity changing sigmoidally with ligand concentration. The spectra can be used to define the high and low-affinity states of the enzyme (which seems to conform with a two-state scheme), and the circumstances under which either one predominates are nicely reconciled with earlier inferences. The Cotton effect associated with the cofactor, NADPH, also responds to the attachment of ligands.

DNA SEQUENCES

Slipped Circles and Sticky Ends

from a Correspondent

ONE of the continuing triumphs of present day molecular biology is the increasing understanding of the fine

structure of the genome of eukaryotic cells. The cytological studies of lampbrush chromosomes by Callan were a major starting point, and led him to suggest that in many instances numerous copies of each gene were present in eukaryotic genomes, represented as tandemly repeated sequences within the DNA. The presence of substantial amounts of sequence reiteration within eukaryotic DNA was supported by the well known studies of its renaturation kinetics, carried out by Britten and his colleagues, and it is also now clear that in various satellite and ribosomal DNAs there is tandem repetition of similar or identical sequences.

Now, in some brilliantly conceived experiments, C. A. Thomas *et al.* (*J. Mol. Biol.*, **51**, 621; 1970) have been able to demonstrate in a fairly direct way that such tandemly repeated sequences must in fact make up a large proportion of the genome of several eukaryotic species which they have studied. The experimental rationale was as follows. If a considerable proportion of eukaryotic DNA is indeed made up of identical tandemly repeated sequences, then it should be possible to convert large fragments of such DNA into circles, by limited treatment with strand-specific exonucleases to expose single-stranded regions at the ends of the fragments. These could then anneal together because parts of their sequences would be complementary. Thomas and his colleagues term this procedure "folding". An alternative way of producing circles would be to denature the DNA fragments and then re-anneal them. In repetitive DNA, "slippage" between the strands would be likely to occur so that single-stranded ends would be produced which could form duplexes with each other. In both instances, it would be possible to see the circles by electron microscopy.

They put theory into practice with DNA from *Necturus*, trout sperm, salmon sperm and calf thymus. Degradation of sheared DNA with exonuclease III (exposing 5'-ended single strands) or λ exonuclease (exposing 3'-ended strands) to a varying extent (5-25 per cent) followed by annealing yielded a plethora of circles in all cases, with some lariots and polyrings to boot. The overall frequency of circular DNA structures was not less than 20 per cent and as much as 35 per cent in the case of *Necturus*. Numerous examples of the structures are shown in some extremely attractive electron micrographs. The necessary control experiments which were carried out with undigested fragments and with prokaryotic DNA (from *Escherichia coli*, *Bacillus subtilis* and bacteriophage T7), gave far lower values (around 5 per cent for the undigested controls and 0.5-1.4 per cent for the prokaryotic DNAs). Similar results were obtained with the slipped circle technique, although no quantitative studies could be carried out because of the large fraction of DNA remaining denatured.

Thomas *et al.* also studied the interesting question of whether these repeated stretches were distributed throughout the eukaryotic genome, or whether they were particularly associated with any compositional class of the DNA. They found, at least for *Necturus* DNA, that all the fractions which they took from a peak on a CsCl gradient possessed a similar ability to cyclize. The dimensions of the circles could be calculated from the electron micrographs. Most of the circles were less than 2 μ m, but some were 5 μ m or even 20 μ m in circumference. They hazard a guess that some of the gene families in trout DNA encompass 4-5 μ m, and as much as 8-10 μ m in *Necturus*. Thomas

et al. suggest that the efficiency of the cyclization is only 50 per cent on a generous estimate. Therefore, as much as 40–70 per cent of all the fragments of DNA contain tandemly repetitious sequences. How such sequences are kept identical remains a mystery.

Meanwhile down at the bacteriophage genome (still no mean problem), R. Wu reports (*J. Mol. Biol.*, **51**, 501; 1970) his *tour de force* with the nucleotide sequences of the sticky ends of the DNAs from bacteriophages λ and 186. His method, which is potentially a general technique for the nucleotide sequence analysis of DNA, was to build the complementary strand on to the single-stranded regions which protrude from the ends of the DNA duplexes, and are a common feature of bacteriophage DNAs. He used *E. coli* DNA polymerase and ^{32}P -labelled deoxyribonucleoside triphosphates to synthesize these complementary strands *in vitro*. In the first instance he determined that the cohesive ends in the λ and 186 DNA each contained twelve and seventeen nucleotides respectively, from measurements of the incorporation of the radioactive nucleotides. He was able to deduce some of the nucleotide sequence of both the λ and 186 ends by nearest neighbour analysis, using only one out of the four radioactive triphosphates in the incorporation. Some further help was obtained from the fact that the two cohesive ends are known to be entirely complementary to each other in both bacteriophages. The *coup de grâce* (well, nearly) was achieved by digesting the DNAs with micrococcal nuclease, and partially digesting the various labelled terminal fragments so obtained with venom phosphodiesterase. He reports two thirds of the sequence of the λ DNA ends, pGGCGGCG being the sequence complementary to the inner eight nucleotides in the right-hand protruding strand, pCGCCGCC. In 186 DNA, the first four nucleotides added to the right-hand end had the sequence pGGCG.

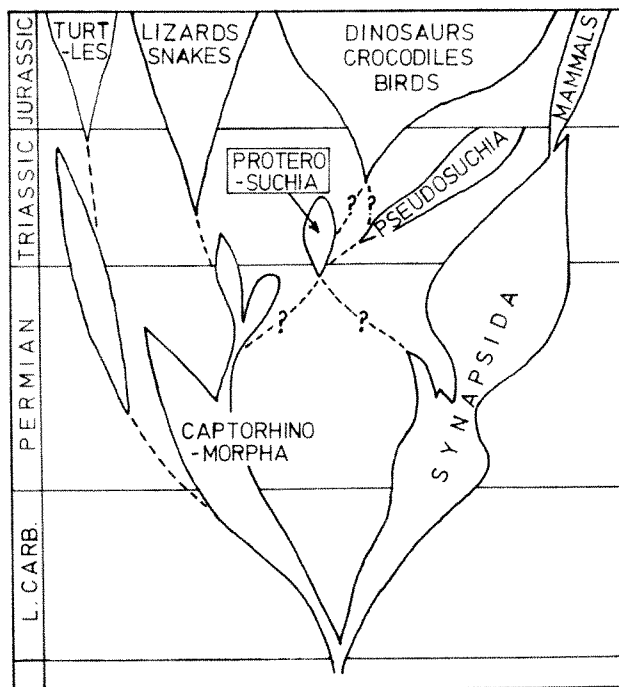

ARCHOSAURS

Divergent Evolution

from our Vertebrate Palaeontology Correspondent

THE course of evolution of mammals from synapsid (mammal-like) reptiles is now known in enough detail that a number of papers have been devoted to the problem of where to draw the taxonomic dividing line between the two groups. The ancestry of the great archosaurian group of reptiles, which includes dinosaurs, crocodiles and the ancestors of the birds, is far more uncertain. This is partly, at least, because the earliest known archosaur group, the Lower Triassic Proterosuchia, comprises two already divergently specialized types. Furthermore, even the composition of the Proterosuchia, as well as the classification of the proterosuchians themselves, has been very differently viewed by past authors. These facts add complexity to the problem of defining the ancestry of the archosaurs as a whole, and also to the problem of the precise evolutionary pathway between the early archosaurs and the more advanced, later forms.

A welcome first step towards solving these problems is the recent discussion of the composition and classification of the Proterosuchia by A. J. Charig and O. A. Reig (*Biol. J. Linn. Soc.*, **2**, 77; 1970). The two different types of proterosuchian are exemplified by *Chasmosaurus* and *Erythrosuchus*. The former is a medium

Ancestry of the Archosauria.

to large sized, slender animal, crocodile-like in appearance and probably also in its way of life, with a long, low skull, a long neck and a short tail. *Erythrosuchus*, on the other hand, is a large to very large, clumsily built carnivore, rather like a hippopotamus in its general build; it has a massive skull, a short neck and a long tail. The fact that *Chasmosaurus* is found slightly earlier than the first known erythrosuchid, and the existence of two genera which bridge the evolutionary gap between the two families, suggests that the erythrosuchids may have evolved from *Chasmosaurus*-like forms.

In another, more controversial paper, Reig tackles the problems of the ancestry of the proterosuchians and of their relationship to the pseudosuchians and saurischian dinosaurs (*Bull. Mus. Comp. Zool. Harv.*, **139**, 229; 1970). It is commonly believed that the archosaurs evolved from the earlier captorhinomorph reptiles, which are primitive in many ways. Though he agrees that this is possible, Reig believes that a better case can be made for the evolution of the proterosuchians from the varanopsids—members of the synapsid group of reptiles. He points out that the varanopsids possess a number of characteristics found in the proterosuchian archosaurs, such as the position of the jaw articulation, well posterior to the level of the occipital condyle, so that the occiput slopes forwards and there is no notch for the tympanic membrane, and also the presence of an ant-orbital opening in the skull and possibly also of an opening in the side of the lower jaw.

Palaeontologists are likely to view Reig's theory with considerable scepticism, because it would imply that the peculiar spiral division of the base of the aortic arches (which is found in all living reptiles) must have evolved twice—once in the captorhinomorph ancestors of turtles, lizards and snakes, and again in the line leading from the synapsids to the archosaurs (including crocodiles and birds). This would

follow from the fact that this specialization of the aortic arches is not found in the mammals nor, by inference, in their synapsid ancestors. Unfortunately, Reig does not even mention this difficulty. He also believes that the proterosuchians are the direct ancestors of both the crocodiles and the sauropod dinosaurs, whereas most other workers believe that these groups evolved from the Pseudosuchia. Whether right or wrong, Reig's views will stimulate further discussion and argument.

COMPUTERS

Human Needs are What Matter

A NEW way of teaching children how to think with a computer was described by Professor Seymour Papert of the Massachusetts Institute of Technology at a conference on man-computer interaction held at Teddington, London, from September 2 to 4. His idea is that by letting children re-invent the rules of geometry or grammar through a computer program they will become instilled with the same sense of excitement experienced by scientists and technologists.

One of the evils of the present educational system, according to Professor Papert, is that it classifies children as failures if they cannot master quickly a desired subject and this causes despair and disenchantment. In his system children are taught to write their own computer programs in a very simple computer language called LOGO, and are made aware from the outset of the art of debugging a program. Professor Papert cited a simple program to design a man from a choice of geometrical operations on a set of matchsticks: by displaying the drawing on a cathode ray screen the child may retrace his steps and discover, if need be, where his geometry went wrong. Although the novelty of the scheme may have induced special interest, Professor Papert is greatly encouraged with the results of his first class of eight year olds and next year he hopes to maintain his first year-long course with a class of forty children.

However much medical practitioners may flinch at the thought, computers seem to be endowed with a charming bedside manner. This was the conclusion presented by Dr C. H. Evans of the National Physical Laboratory and Professor W. I. Card of the University of Glasgow who have been investigating how patients with suspected ulcers react to question and answer sessions with a computer. Once familiar with the button pushing routine, patients seemed to warm to the chatty program devised by Dr Evans to get patients to divulge their symptoms. Dr Evans and his colleagues are still working on how factors like response time could be related to the intuitive side of a doctor's interrogation, but Dr Evans pointed out that there seem to be some important advantages in using computers, apart from saving hospital time. A difference in class between doctor and patient can seriously inhibit communication, he said, and doctors are sometimes also irritable and tired. Computers are cool and classless, on the other hand.

It may soon be possible to translate mechanical shorthand into normal English on a computer, according to Dr W. L. Price of the National Physical Laboratory, which would provide barristers with on-the-spot transcripts of evidence and speed up the production of

official documents such as Hansard. Several major hurdles still have to be overcome to transpose the twenty-nine symbols of palantype, the British form of mechanical shorthand, into proper English. The computer operates by comparing the incoming sounds with a dictionary of words, and difficulties arise with homophonic words like "insight" and "incite". The group at NPL have programmed in a limited amount of syntax analysis by allowing for the scanning of adjacent words when an ambiguous word appears, and although the system is still too imperfect for satisfactory usage, Dr Price is hopeful that a viable version can be produced.

Work is also in progress at NPL on speech recognition by computers, a yet more hazardous task. Professor C. Longuet-Higgins of the Machine Intelligence Unit at the University of Edinburgh maintained indeed that the chasm between the inconsistencies of natural language and the cold logic of computers was so wide that it was wiser not to try to bridge the gap. "Computers are ideal tools for studying natural language," he said, "but not for understanding it." He stressed that comprehension of English rests on an immense fund of common knowledge between conversants, and he mocked the computer's innocence in the face of the two statements, "Nothing is better than a good square meal", and "A sandwich is better than nothing".

SEISMOLOGY

Numerical Earth

from our Geophysics Correspondent

THE International Symposia on Geophysical Theory and Computers have, since their inception, been fairly small affairs, rarely attracting more than a hundred geophysicists, unlike the preposterous jamborees that most international meetings have become. The reason for the relative smallness is the highly specialized subject that is being dealt with, but out of this modesty in size comes also a quite remarkable camaraderie. The atmosphere is such that it is really true that coffee table conversations get converted into research effort and next year's papers.

This year's meeting, the seventh in the series, was held in Stockholm from August 17 to 28. Most aspects of geophysics were covered, but as usual seismology was strongly dominant. Problems of data inversion, wave propagation and array processing received most attention. A notable exception was a paper by T. Dahlen (Cambridge) on excitation of the Chandler wobble by earthquakes. This controversial topic draws on the whole range of applied mathematics, before anything meaningful can be said. Dahlen dealt with a "realistic" Earth model and showed that the changes in products of inertia arising from displacements caused by large earthquakes are compatible with the amplitudes of renewal of Eulerian nutation (a few metres shift in the North Pole) frequently observed. Dahlen remarked, however, that there are still difficulties of analysis and interpretation which need more refined study of the data on which these ideas are founded.

Another paper which attracted much attention was by R. Burridge (Cambridge) on the form of radiation from earthquake faults. This problem is at best

difficult to handle theoretically, let alone numerically, so the work presented was of great interest in that it now seems possible to specify plausible fault models and predict signal waveforms. The interaction of a fault with the free surface was shown to produce the most striking features in the far field radiation.

Techniques for inverting geophysical data and for making statements about the uniqueness or resolving power of such inversions have received wide study in the past five years following the complementary attacks on the problem by Backus and Gilbert in La Jolla and Keilis-Borok's school in Moscow. Papers on inversion and a panel discussion were presented by T. Jordan and D. L. Anderson (Caltech), L. Knopoff (UCLA), F. Press (MIT) and V. Keilis-Borok (Institute of Physics of the Earth). The subject is appealing in that a broad range of attacks can be mounted on it, from the austere theoretical study to the Monte Carlo method. In addition to constraints imposed by the actual data, there are also the somewhat more difficult to inject constraints of relationships between elastic parameters and densities, and "smoothness" criteria. These are matters of much discussion, and the whole led to a thoroughly stimulating session which undoubtedly will be repeated in future years.

A subject which has seen rapid growth in the past few years is array processing of the vast streams of seismic data which are now recorded especially from the Large Aperture Seismic Array (LASA) in Montana and NORSAR in Norway. Papers by R. Baron and S. Francisco (IBM, Washington) described the extensive processing necessary for routine acceptance of such data and H. Bungum (Norwegian Defence Research Establishment) outlined the NORSAR installation. D. Davies (MIT, Lincoln) gave a description of some research uses of arrays in the study of inhomogeneity in the mantle. It has been suggested that arrays, like many other technological innovations, are a tool in search of a user. Extended discussions were held to allow a panel of research workers connected with arrays—E. Husebye (Norway), E. Flinn (Geotech Corporation), D. Corbishley (UK Atomic Energy Establishment) and Davies to put forward and receive new ideas on array applications.

Of the many other papers presented, perhaps the most interesting was a didactic presentation by J. Bazer (Courant Institute, New York) on magneto-elastic wave propagation in both linear and non-linear cases. This field is arguably the most difficult to comprehend of all wave propagation cases and it was greatly to the credit of Dr Bazer that the subject was put over so lucidly to his audience.

In the past the symposium has lived under the financial umbrella of the Upper Mantle Committee, but with the imminent demise of this committee future success will depend heavily on the capability of raising \$15,000 every other year. The scientific merit is assured through the remarkable talents of the organizing secretary, Dr Keilis-Borok, but an imaginative sponsor would be another great asset. This year, through the singular efforts of Dr Bo Jansson, industrial support was forthcoming, particularly from Svenska Handelsbanken and IBM (Sweden). The plans are to return to Stockholm for future meetings and to try to encourage graduate student attendance by travel grants. Potential sponsors who profit by the number-crunching of this group and would like to add their name to the title of this meeting, please note.

WATER CONSERVATION

Natural Reservoirs

from our Geomagnetism Correspondent

THE obvious way to store water for future use is to build a dam. That is man's way; but nature has its own, more impressive, techniques. Ninety-six per cent of all freshwater on the continents is stored below the ground surface in aquifers. To be sure, some of the water which falls onto the continents is lost in run-off; but in the United States, for example, the 7,300 cubic miles of water which rivers annually discharge into the sea represents only 0.4 per cent of the total stored in sub-surface aquifers.

But can man make use of nature's store? The answer to this question is that not only is it possible but in the United States and Israel it is being done. According to Dr Charles L. McGuinness of the US Geological Survey, aquifers now supply about 61,000 million gallons a day, about a fifth of all water used in the United States. Indeed, in some areas, notably southern California and Long Island, New York, more water is being removed from aquifers than nature is replacing. Accordingly, it has become necessary to replenish ground water supplies artificially.

Artificial recharge is being achieved in a variety of ways including injection into pits and wells and the use of structures which divert and spread concentrated water supplies such as rivers, thereby increasing the area over which water can percolate downwards. The precise technique adopted in any given case depends on the nature of the water sources, the sub-surface geological structure, the pattern of subsequent water usage and, of course, cost. Clearly, the sub-surface rocks must not be impervious to water, but at the same time they must not be so porous that the water moves around too freely. And as far as cost is concerned, simple spreading structures are preferable. They are used in California, for example, to give the water more time to filter into the alluvium at the mouths of canyons. In the mid-west and east, on the other hand, conditions are not favourable for water spreading, and relatively expensive injection into wells must be adopted.

Underground reservoirs have several advantages over dams. There are no construction costs and little maintenance is required; the water they yield is relatively stable in temperature and quality; they do not take up valuable surface space which could be used for other purposes; they do not silt up; and the evaporation loss is negligible. Artificial recharge of these reservoirs has its benefits, but also its drawbacks. The obvious benefit is the saving of water which would otherwise be lost to the sea. On the other hand, injection through wells, in particular, is expensive. Another problem, recently highlighted by another US Geological Survey hydrologist, Dr Raymond L. Nace, centres on the quality of water available for injection. Water from rivers often contains sediment which rapidly clogs up wells, necessitating the additional expense of frequent well cleaning. More dangerous, of course, are the man-made impurities—not only those in the original water sources but the industrial wastes separately disposed of underground. Until the precise patterns of sub-surface water movement are known, if ever, the threat of contamination is obvious.

What neither Dr McGuinness nor Dr Nace mentions,

however, is the danger of injection at all. Presumably little harm is likely to result from pure replacement of water; but there is proven danger in injecting fluids where there were none before, however attractive or suitable the geological structure. The series of earthquakes which some years ago struck Denver as a result of underground waste disposal are still fresh in many minds. But even dams are not free from that problem as experience in India, France and Rhodesia has shown.

TECTONICS

A Caribbean Plate?

from our Geomagnetism Correspondent

ALTHOUGH the principal features of plate tectonics are now widely accepted, many details remain to be settled. This week, the US Coast and Geodetic Survey ship *Discoverer*, with its electronic sonar equipment, is being used to probe the bottom and sub-bottom of the Caribbean around Barbados to trace the extension of structural features found during previous studies and, hopefully, to gather evidence which will finally settle the question of whether the Caribbean is a separate crustal plate or is an extension of the South American continental landmass.

If the Caribbean forms a separate crustal plate, as some scientists apparently believe, there would have to be large faults along its northern and southern boundaries. The southern fault, for example, would presumably lie between the southern end of the Lesser Antilles and Venezuela. The *Discoverer*, however, made eighteen crossings over the supposed fault trace during 1968 and 1969 and found no evidence that such a fault actually exists. The data obtained so far thus support the conclusion that the Antilles double island arc system is an offshore extension of

South America. The present traverses should confirm this interpretation.

MICROELECTRONICS

High Hopes for New Device

by our Solid State Physics Correspondents

A NEW type of semiconductor device has been constructed at Bell Telephone Laboratories which promises to be of major importance in the design of computers and communications systems. It is based on an idea revealed earlier this year called charge coupling which enables a series of metal-oxide-semiconductor (MOS) elements to be linked together in a way that removes for the first time the need for separate capacitors between elements.

It is this use of the MOS element as its own capacitor for storing charge that is particularly important, both from the point of view of performance and of cost. M. F. Tompsett, G. F. Amelio and G. E. Smith (*Appl. Phys. Lett.*, 17, 111; 1970) have fabricated an eight bit shift register based on this concept, and have achieved transfer efficiencies of greater than 98 per cent for times of less than 100 ns, comparable with those for existing shift registers. They accomplished this with a design which, they say, was chosen for ease of construction rather than high performance.

The special feature of charge coupled devices lies in the way that charges are stored and passed along the device. The structure used by Tompsett *et al.* consisted of a row of MOS capacitors on a substrate of *n*-type silicon with a *p-n* junction at either end. Application of a potential to one of the capacitors creates a region depleted in electrons under the capacitor, and by varying the potential along the array the holes thus formed can be transferred to neighbouring capacitors. The key to the efficiency of this process is the generation and maintenance of a depletion region under the electrodes.

The construction of these devices hinges on the production of highly perfect oxide surfaces and silicon substrates. Although the team at Bell Telephone Laboratories seem to have overcome the major hurdle the exact way in which the performance of the array depends on different parameters in the system is still not clear. Tompsett *et al.* have found, however, that the transfer efficiency depends quite sensitively on the depth and shape of the voltage drops of the transfer pulses, and that greater efficiency is induced if the surface potential of the silicon is lowered during charge transfer.

The first experiments have demonstrated the use of the eight bit shift register as a 48 μ s delay line and as a display for an image optically focused on to the device. The most exciting possibility for these devices lies naturally in their use as shift registers and for logic operations in computers. Shift registers, after all, perform the meat of a computer calculation and are involved in the process of time sharing. Storage periods of only a few microseconds are adequate here. But the successful demonstration of the line-imaging capability of the device, in which the spatial form of an image is translated into a train of electrical pulses, must raise hopes for the optical possibilities of the system, and elevate once again the question of when a solid state replacement for the cathode ray tube will eventually be produced.

This week's investigations by the US Coast and Geodetic Survey ship *Discoverer* will centre around the Antilles double island arc system, an island arc comprising both an inner volcanic belt and an outer sedimentary belt. Part of this double island arc system rises above the water and forms the islands of Guadeloupe, Dominica, Martinique, St Lucia, St Vincent, Barbados, Grenada and Tobago. Barbados and Tobago are part of the outer sedimentary belt; the other islands are part of the inner volcanic belt. The islands, or elevated portions of the belts, are shown as broken lines; the submerged portions as solid lines.

Ion Cyclotron Resonance Mass Spectrometry

by

GILLIAN C. GOODE
REBECCA M. O'MALLEY
A. J. FERRER-CORREIA
K. R. JENNINGS

Department of Chemistry,
The University,
Sheffield S3 7HF

This relatively new form of mass spectrometry is proving to be valuable in several branches of chemistry. This review shows that the technique has already yielded some useful data.

In a mass spectrometer, ions produced from neutral species, usually by transfer of energy from an electron beam, are separated according to their mass-to-charge ratio (m/e) and their relative abundances determined. In a standard magnetic deflexion instrument, ions are subjected to a large accelerating potential after which they are separated by passing them through a magnetic field so that only ions of a given m/e are brought to focus at the collector slit. Mass spectra are obtained by scanning either the accelerating potential or the magnetic field. Recently, increasing use has been made of ion cyclotron resonance (ICR) mass spectrometers, the mode of operation and applications of which are very different from those of a conventional analytical instrument¹⁻⁴. (The most widely used instrument is the Varian Associates V-5900 ICR mass spectrometer designed by Dr P. M. Llewellyn.) The principal area of application has been in the study of collision processes of ions which, in addition to their intrinsic interest, are important in radiation chemistry and in the chemistry of plasmas, flames and the upper atmosphere.

Principles of Operation

An ion which is moving in a plane perpendicular to a uniform magnetic field is constrained to follow a circular path, the frequency ω_c of which is given by

$$\omega_c = eB/m \quad (1)$$

where B is the magnetic field strength and m/e is the mass-to-charge ratio of the ion. The frequency ω_c is the cyclotron resonance frequency and for a given magnetic field strength, it is characteristic of ions of a given m/e . If an oscillating electric field is applied perpendicular to the direction of the magnetic field, ions of a given m/e will absorb energy when the frequency of this field, ω_1 , is equal to ω_c . This resonance phenomenon is the basis of the detection system in an ICR mass spectrometer: in the instrument, the source region is separated from the analyser region in order to minimize ion trapping and space charge effects. A small electric field is applied perpendicular to the direction of the magnetic field so that the ion follows a cycloidal path, and the overall drift velocity V_D of an ion is given by

$$V_D = l/\tau = E/B \quad (2)$$

where l is the length of the analyser region, τ is the time spent by an ion in this region, and E is the electric field strength.

Fig. 1 shows a standard three-section cell comprised of the source, analyser and ion collector regions. Electrons emitted by a rhenium filament are accelerated through a known variable potential and are collimated by the magnetic field; ions are produced by these electrons along the 2.5 cm of the beam within the cell. All the ions follow a cycloidal path, but space charge repulsion between the similarly charged ions results in a loss of ions in the direction of the magnetic field unless a small trapping potential of the same sign as that of the ions under study is applied to the sides of the cell. This trapping potential is removed in the ion collector region so that ions are collected on the side plates, making it possible to monitor the total ion current. The oscillating electric field is applied to the analyser region: if $\omega_1 \neq \omega_c$, no power absorption occurs and the ion path is as shown schematically in Fig. 2a. For those ions for which $\omega_1 = \omega_c$, energy is absorbed and the ion path for low oscillating field strengths is as shown in Fig. 2b. At very high field strengths, the power absorption is great enough to cause the ions to be lost by striking

Fig. 1. a, Side view of ICR cell in which the observing oscillator ω_1 is located in the analyser region A, and the irradiating oscillator ω_2 is connected either to the source region S or the analyser region A. The total ion current is measured at T in collector region C. V_S and V_A are the source and analyser drift potentials respectively and P is the electron beam. b, End-on view of the cell showing the directions of the electric and magnetic fields and the ion motion. X and Y are the drift and trapping plates respectively.

the upper and lower plates of the cell, and this can be used to obtain a "total ion current (TIC) spectrum" by monitoring the reduction in total ion current as ions of different m/e are swept out of the analyser region.

Single resonance spectra are usually obtained by holding ω_1 constant and scanning the magnetic field. To improve the signal-to-noise ratio, a phase-sensitive detector is used to measure power absorption. The power absorption can be modulated by using one of several different methods, for example pulsing the source drift field or modulating the electron beam energy. Modulation of the magnetic field gives rise to a derivative spectrum and is preferred for quantitative work because it has least effect on the ion motion and ion density. Typical operating conditions for the observation of Ar^+ ($m/e = 40$) are given in Table 1.

Table 1. TYPICAL OPERATING CONDITIONS IN OBSERVATION OF Ar^+

$m/e = 40$	$B = 8,000$ gauss
$\omega_e = 307$ kHz	Drift field $E = 0.25$ V cm $^{-1}$
$V_D = 3.1 \times 10^3$ cm s $^{-1}$	Analysing region $l = 6.35$ cm
$\tau = 2 \times 10^{-3}$ s	

Radius of non-resonant orbit $r = 0.02$ cm.

Some of the differences between this instrument and the standard analytical mass spectrometer can now be appreciated. The absence of slits results in very high sensitivity so that trap currents are typically 10^{-7} – 10^{-8} A rather than the 10^{-4} A used in analytical instruments. The very long cycloidal path length (typically 10–100 m) means that collision phenomena are important at pressures in the region of 10^{-6} torr so that products of ion-molecule reactions are readily observed. Furthermore, the low drift velocity makes it possible to observe ions milliseconds after formation rather than microseconds as in an analytical instrument. The very low potentials and the magnetic field can easily be reversed, and so the high sensitivity can be utilized in the study of negative ions.

Whereas in an analytical instrument the resolution depends on such factors as beam width and slit width, it depends on quite different instrumental parameters in an ICR mass spectrometer.

Fig. 2. *a*, Ion motion in the absence of the r.f. field; *b*, ion motion when $\omega_1 = \omega_c$.

Various definitions of resolution are common in mass spectrometry, but in ICR mass spectrometry the resolution $\rho (=M/\Delta M)$ is put equal to $\omega_c/\Delta\omega_{\frac{1}{2}}$, where ω_c is the cyclotron resonance frequency and $\Delta\omega_{\frac{1}{2}}$ is the half-width of the peak in frequency units at half the maximum height. This can be shown to be approximately equal to $2.78/\tau$ where τ is the time during which the ions absorb energy⁵. If τ is the time taken for the ions to pass through the analyser region of the cell,

$$\rho = M/\Delta M = \omega_c/\Delta\omega_{\frac{1}{2}} = \frac{\tau Be}{2.78m} = \frac{lB^2e}{2.78Em} \quad (3)$$

and in typical conditions is in the range 500–2,000. If the ions undergo decomposition during passage through the cell, or if they suffer frequent collisions with neutral species, τ may be significantly shorter than the time required for the ions to pass through the cell, thereby leading to a reduction in resolution.

Two other techniques which have no parallel in conventional mass spectrometry are the double resonance technique⁶ and the ion ejection technique⁷. In almost all cases, the rate constant for an ion-molecule reaction $A^+ + B \rightarrow C^+ + D$ varies with the translational energy of the reactant ion, A^+ , and use can be made of this fact in obtaining double resonance spectra. The magnetic field is adjusted until C^+ ions absorb energy from the observing oscillator of frequency ω_1 .

A second radio frequency field is applied to the source region of the cell, and the frequency of this is varied at constant magnetic field strength. When the frequency of this oscillator, ω_2 , equals the cyclotron resonance frequency of A^+ ions at the particular magnetic field strength in use, A^+ ions absorb energy, causing their translational energy to increase. This will result in a change in the number of C^+ ions observed, provided they are related to A^+ by the reaction we have shown. At a fixed magnetic field strength,

$$m_A/m_C = \omega_1/\omega_2$$

so that by scanning ω_2 , different precursors of C^+ can readily be identified.

Fig. 3. Double resonance spectra for increasing amplitudes of radio frequency ω_2 for the reaction $\text{DH}^+ + \text{DH} \rightarrow \text{DH}_2^+ + \text{D}$.

If the double resonance signal is due solely to the change in rate constant with increase of translational energy, then the sign of the signal can be interpreted as the sign of the rate of change of the rate constant with the translational energy of the reactant ion, dk/dE_{tr} . But effects arising from ion losses and changes in space charge effects when energy is absorbed may complicate the interpretation.

Fig. 3 shows the double resonance spectrum obtained for the reaction

at increasing amplitudes of the irradiating field. The increase in yield of DH_2^+ ions at low amplitudes suggests that dk/dE_{tr} is positive for this reaction. At higher amplitudes, DH^+ ions gain sufficient energy to be lost from the cell, thereby reducing both the yield of DH_2^+ ions and the total ion current. It is consequently important to monitor the total ion current during an ICDR experiment (unpublished work of G. C. G., A. J. F.-C. and K. R. J.).

Although double resonance spectra allow the identification of ion-molecule reactions, they do not provide a means of determining the relative importance of different reactions leading to the same product ion.

In favourable cases, this can be accomplished by using the ion ejection technique by which ions of a given m/e ratio can be removed selectively from the cell. In addition to the cycloidal motion perpendicular to the direction of the magnetic field, ions undergo simple harmonic motion in the direction of the field in the presence of a trapping potential V_T . The frequency ω_T of this oscillatory motion is given by

$$\omega_T = (4V_T e / md^2)^{1/2} \quad (5)$$

where d is the separation of the trapping plates, but the amplitude is usually insufficient for ions to be lost at the trapping plates. This amplitude, however, can be increased if an oscillating field of frequency ω_T is applied to the trapping plates, so that ions of a given m/e ratio are ejected from the cell. Because ω_T is independent of the magnetic field strength, spectra can be obtained in the normal manner, but in the absence of the ejected ion. By ejecting different ions in turn and observing the variation of the yield of a secondary ion, the relative importance of the ejected ions as precursors of the secondary ion can be determined. The major limitation of the ion ejection technique at present is the very low resolution obtainable, about five, which usually means that more than one ion is wholly or partly ejected.

The quantitative interpretation of ICR spectra is quite complicated and varies with the operating conditions⁸⁻¹⁰, but in the limiting conditions of low ion current density, low conversion and low pressure, the argument is essentially as follows. The peak height is proportional to the power absorption in an ICR spectrum, and at resonance, this is given by

$$A(\omega_c) = Ie^2\epsilon^2\tau^2/8m \quad (6)$$

for ions of mass-to-charge ratio m/e , where I is the number entering or leaving the analyser region each second, τ is the time spent in the analyser region and ϵ is the radio frequency field strength. From equations (1) and (2), $\tau \propto m$ for magnetic field scans, so that $A(\omega_c) \propto Im$, if ϵ is constant. Although this argument is approximately correct for primary ions at low conversions, an additional correction is necessary for secondary ions because their yields are approximately proportional to the time which elapses between the formation of primary ions and the average time at which absorption by secondary ions of a given m/e is observed. In a magnetic scan, this time is directly proportional to the mass of the secondary ion, so that for secondary ions, $A(\omega_c) \propto m^2$. In these conditions, therefore, peak heights can be normalized by dividing by m in the case of primary ions and by m^2 in the case of secondary ions. In the case of "TIC spectra", the radio frequency field is used merely to remove ions of a given m/e ratio so that for primary ions no mass correction is necessary, but for secondary ions the signals are normalized by dividing by m in order to correct for the different times allowed for their formation during a magnetic scan. High ion densities, pressures and conversions all serve to complicate the quantitative interpretation of peak heights.

Applications of ICR Mass Spectrometry

One of the chief applications of ICR mass spectrometry has been in the qualitative and semi-quantitative study of ion-molecule reactions in simple systems, using the double resonance and ion ejection techniques to characterize reaction sequences. In normal operating conditions, the translational energies of reactant ions are only slightly in excess of thermal, so that only products

of thermoneutral and exothermic ion-molecule reactions are observed. This contrasts with the ion-repeller field method used in medium and high pressure sources in which translational energies of reactant ions at the exit slit are commonly as high as 2-3 eV. ICR studies of this type will be exemplified by considering ion-molecule reactions in the three systems C_2H_4 , C_2H_3Cl and C_2H_3F .

In the ethylene system^{4,10}, the only primary ion produced at low electron energies is the molecular ion, $C_2H_4^+$. At pressures only a little above 10^{-6} torr, sufficient numbers of collisions occur between these ions and C_2H_4 molecules for the two secondary ions $C_3H_5^+$ and $C_4H_7^+$ to be readily observable. These ions are formed in the reactions

and the observed peak intensities for the two secondary ions lead to $k_2/k_3 =$ approximately 9.5, in good agreement with values obtained by other techniques. Results obtained⁹ with mixtures of C_2H_4 and C_2D_4 showed that the experimental product distribution was very close to that expected on the basis of complete H-D randomization in the collision complex, indicating that the H and D atoms become equivalent in the collision complex. Negative double resonance signals indicated that the rate constants for reactions (2) and (3) decreased as the translational energy of $C_2H_4^+$ increased, whereas positive double resonance signals were obtained for all ions formed in charge-transfer processes. The variations in yields of secondary ions during double resonance experiments suggested that charge transfer processes and the exothermic ion-molecule reactions (2) and (3) occurred competitively at low translational energies of the reactant ion. Typical spectra are shown in Fig. 4.

One of the first systems to be studied by ICR mass spectrometry was chloroethylene², and although only qualitative results were obtained it showed the great potential of the double resonance technique in determining complex reaction sequences. The three major reactions of the molecular ion were found to be

The most common type of reaction of other ions in this system was that analogous to reaction (6), that is

The double resonance technique was used to show that the two Cl atoms become equivalent in the collision complex, for example if $(X^{35}Cl)^+$ reacts with $M^{37}Cl$, the ^{35}Cl atom is not preferentially retained in the charged product, but the two Cl atoms are statistically distributed between the charged and neutral products of the reaction.

Whereas the elimination of HCl from the collision complex is a major reaction path in the chloroethylene system, the corresponding reaction in the fluoroethylene system³ accounts for only about 2 per cent of the reaction products. No reaction analogous to reaction (5) occurs, and the three major reactions of the molecular ion are all

Fig. 4. *a* and *b*, Low pressure spectra of ethylene at 12 eV and 20 eV respectively. *c* and *d*, High pressure spectra of ethylene at 12 eV and 20 eV respectively. *e*, Double resonance spectrum of $m/e = 41^+$; $\omega_1 = 226$ kHz, $\omega_2 = 331$ kHz, showing that the precursor is the molecular ion, $m/e = 28^+$.

analogous to reaction (4) in the chloroethylene system and reaction (2) in the ethylene system:

The relative rate constants for reactions (8), (9) and (10) were found to be 0.59, 0.23 and 0.18 respectively. Reactions of other ions with $\text{C}_2\text{H}_3\text{F}$ are frequently analogous to reaction (7), HF being the neutral species most commonly eliminated.

Reactions which occur in a mixture of ethylene and fluoroethylene illustrate the use of the ion-ejection tech-

nique. A major product is the $\text{C}_3\text{H}_4\text{F}^+$ ion ($m/e = 59$) which may be formed in reaction (9) or in the reactions

The yield of this ion can be observed in the presence of both reactant ions and also when either ion is ejected as is shown in Fig. 5. In this way, it can be shown that reaction (12) is the principal source of $\text{C}_3\text{H}_4\text{F}^+$ ions in the mixture, for the $m/e = 59$ intensity decreases only slightly when the C_2H_4^+ ion is completely ejected (unpublished work of A. J. F-C. and K. R. J.).

Because the translational energies of reactant ions in ICR instruments are close to thermal, product ion distributions may differ from those found using medium pressure sources and the ion-repeller technique. For example, in the propyne system, the formation of C_3H_5^+ in the reaction

is a major process in a medium pressure source at ion exit energies of 1.7 eV (ref. 11), but this is a minor process in an ICR instrument¹². The study of endothermic ion-molecule reactions in ICR instruments, however, is possible by using a technique introduced recently^{13,14} in which the translational energies of reactant ions are increased by subjecting them to a pulse of radio frequency energy at the cyclotron resonance frequency of the ion. A terminal translational energy of several electron volts can be attained during the pulse and reaction occurs subsequently as the ions pass down the drift tube.

A major use of ICR mass spectrometry has been for obtaining data of thermodynamic interest, such as proton and hydrogen affinities, relative gas phase acidities and electron affinities. The proton affinity (P) of a molecule (M) is defined as the negative of the enthalpy change in the reaction

and the hydrogen affinity (H) of an ion (M^+) is similarly defined for the reaction

Fig. 5. Ion ejection in a mixture of fluoroethylene and ethylene.

The following two reactions can be observed in an ICR instrument, using the double resonance technique:

Because the translational energies of the reactant ions are approximately thermal, these two reactions must be thermoneutral or exothermic. When used in conjunction with other thermochemical data, the observation¹⁵ of the occurrence of reactions (16) and (17) leads to $\Delta H_f(\text{H}_3\text{O}^+) = 149 \text{ kcal} = \text{one's mole}^{-1}$, $P(\text{H}_2\text{O}) = 164 \pm 4 \text{ kcal} = \text{one's mole}^{-1}$ and $H(\text{H}_2\text{O}^+) = 141 \pm 4 \text{ kcal} = \text{one's mole}^{-1}$. Similar use of the two reactions

leads to values of $\Delta H_f(\text{H}_3\text{S}^+) = 181\text{--}184 \text{ kcal} = \text{one's mole}^{-1}$, $P(\text{H}_2\text{S}) = 178 \pm 2 \text{ kcal} = \text{one's mole}^{-1}$ and $H(\text{H}_2\text{S}^+) = 106 \pm 2 \text{ kcal} = \text{one's mole}^{-1}$.

The same technique can be used to obtain qualitative information about relative gas-phase acidities¹⁶ of organic compounds such as alcohols and amines by making use of reactions of the type

For a particular pair of substances, HA and HB, reaction (19) is usually found to occur in the forward or reverse direction only. For example, if reaction (19) occurs in the forward direction only, the proton affinity of B^- is greater than that of A^- , or in other words, HA is a stronger acid than HB. In the case of the alcohols, it was possible to show that the relative acidities were in the order

This is the reverse of the order found in aqueous solution and indicates the importance of solvation effects in determining ionic stabilities in solution. If it is assumed that $D(\text{RO}\cdot\text{H})$ is essentially constant in this series, then the relative acidities will reflect the relative electron affinities of the $\text{RO}\cdot$ radicals.

It is frequently found that ions of identical mass and isotopic composition are formed in the mass spectra of different compounds, but from a consideration of the reactions leading to their formation, it is possible that the structures of the ions differ. If it is assumed that ions of different structure undergo different ion-molecule reactions, differences can be detected quite readily by ICR mass spectrometry. This method has been applied recently¹⁷ to the study of reactions of $\text{C}_3\text{H}_6\text{O}^+$ ions produced in different reactions, for which the following structures have been proposed:

It is assumed that the molecular ion of acetone has the structure (I), and there is good evidence that $\text{C}_3\text{H}_6\text{O}^+$ ions produced from 2-hexanone through a McLafferty rearrangement have the structure (II). The $\text{C}_3\text{H}_6\text{O}^+$ ions formed from 5-nonanone by a double McLafferty rearrangement may have the structure (III), although this ion may isomerize to (II) quite readily. By working with a

mixture of CD_3COCD_3 and $\text{n-C}_4\text{H}_7\text{COCH}_3$, it is possible to produce $\text{C}_3\text{D}_6\text{O}^+$ ions of structure (I) and $\text{C}_3\text{H}_6\text{O}^+$ ions of structure (II), thereby allowing one to distinguish many of their reactions. It was found that of the three possible reactions

reaction (21) was the only one which occurs, indicating that this condensation reaction is specific for the keto-form of the ion (I). Several other reactions were found which also distinguish the ions of structures (I) and (II), but no evidence could be found for the independent existence of ions of structure (III), which behaved in all their reactions as if they existed in the enol form, structure (II).

This account indicates the wide range of application of ICR mass spectrometry in the study of the chemistry of ions in the gas phase. Progress has been made recently in the determination of absolute rate constants of ion-molecule reactions in simple systems^{9,10,18,19}, although the analytical expressions are rather complicated if more than one product is formed. Preliminary studies of threshold excitation spectra of neutrals below the ionization limit^{20,21}, and of Penning ionization processes have also been reported²². The open construction of the cell and the absence of discrimination effects at slits are features of the technique which are only just beginning to be explored and it is to be expected that an increasing range of applications for ICR mass spectrometry will be found during the next few years.

Electron density distributions for the M₄ isoenzyme of LDH reveal details of the conformation of the subunit, boundaries between the subunits, and features relevant to the binding of coenzyme and substrate.

LACTATE dehydrogenase (EC 1.1.1.27) is an NAD-dependent enzyme catalysing interconversion of lactate and pyruvate in the glycolytic pathway

The enzyme is a tetramer of molecular weight 140,000. Each subunit is capable of binding one molecule of coenzyme and reacts independently^{1,2}. Two subunit types with different electrophoretic mobilities are present in tissue^{3,4}; the M type predominates in skeletal muscle and the H type in heart. Five isoenzymes have been isolated of types H₄, H₃M, H₂M₂, HM₃, and M₄. Enzymatic, immunological, physical and chemical properties are more alike among H or M isoenzymes from different species than between H and M forms of the same species⁵⁻⁸.

An obligatory binding order of coenzyme followed by substrate has been shown for lactate dehydrogenase^{9,10}. A conformational change induced by the AMP portion of the coenzyme permits subsequent binding of nicotinamide¹¹. Isomerization of the enzyme-NADH complex is rate limiting for lactate oxidation at pH 6, whereas for pyruvate reduction the rate limiting steps have been suggested to be the formation of enzyme-NADH-pyruvate at alkaline pH and the interconversion of two enzyme-NAD isomers at pH 6 (ref. 12). The formation and properties of an abortive enzyme-NAD-pyruvate ternary complex have not been studied.

The amino-acid residues involved in the activity of lactate dehydrogenase have not been completely characterized. A dodecapeptide containing a thiol group, the mercuration of which inactivates the enzyme, has been isolated for both M₄ and H₄ isoenzymes of several species^{18,19}. Specific tyrosine and histidine residues have also been shown to be important in the activity of pig H₄ lactate dehydrogenase because their modification partially inactivates the enzyme^{20,21}. A complete sequence of lactate dehydrogenase has not yet been determined. The "essential thiol peptide" has been sequenced for several species and found to be homologous: the sequence for the dogfish M₄ isoenzyme is -Ile-Ile-Gly-Ser-Gly-Cys*-Asn-Leu-Asp-Ser-Ala-Arg²². A thirty-six residue C-terminal peptide of pig H₄ LDH has been determined²¹. The C-terminal dipeptide -Lys-Phe, and the N-terminal peptide of approximate sequence acyl-Thr-Ala-Leu-Lys-Asp-Lys-Leu-(Ala, Thr, Ser)-Ile-Gly-His-Leu-Glu-Pro-Gln-Arg have been reported for the dogfish M₄ isoenzyme (ref. 22 and private communication from N. O. Kaplan and W. S. Allison). Complete studies of amino-acid sequence are being carried out for the pig H₄ and M₄ (private communication from G. Pfeleiderer and K. Mella) and the dogfish M₄ isoenzymes (private communication from N. O. Kaplan and W. S. Allison).

The M₄ isoenzyme of lactate dehydrogenase of dogfish (*Squalus acanthias*) has been shown to crystallize in the

space group F422 with one subunit per asymmetric unit and cell dimensions $a=146.8$ Å, $c=155.35$ Å²³. The centre of the tetramer is at the intersection of three mutually perpendicular 2-fold axes. A 5 Å resolution electron density map has already been described^{24,25}. The structure of the enzyme as obtained from an electron density distribution at 2.8 Å resolution is reported here.

A reduction of crystal symmetry is observed on diffusion into crystals of the apo-enzyme of NAD or any fragment of it that incorporates the AMP moiety. This has been interpreted as a small quaternary structural change such that only the molecular 2-fold axis parallel to c is retained²⁴. The position of the coenzyme in these crystals has been determined at 5 Å resolution where the effects of the space group change are sufficiently small to be neglected²⁵. Crystals of the abortive ternary complex enzyme-NAD-pyruvate have been grown with space group P42₁, $a=95.4$ Å, $c=86.1$ Å and one subunit per asymmetric unit. The tetramer again has 222 symmetry²⁶. An electron density map of this form of the enzyme has been calculated (unpublished results of I. E. S., R. K., M. J. A. and M. G. R.) showing the subunit to be very similar to that of the apo-enzyme except for one part of the chain at the edge of the molecule and near the coenzyme binding site.

Structure Determination

Methods of isomorphous replacement similar to those used for other protein structure determinations were used to obtain the protein electron density distribution. Of the heavy atom derivatives described previously^{24,25} the mercuric chloride, methyl mercuric nitrate (MMN), Baker dimercurial (BDM) and dimercuric acetate (DMA) (partial data) derivatives were used in the 2.8 Å calculations. Low resolution native enzyme data were ob-

Fig. 1. Variation of anomalous dispersion, as measured by the refined value for $\Delta f''/(f + \Delta f')$, with $\sin \theta$. ●—●, BDM; ○—○, DMA; ×—×, HgCl₂; ●—●, MMN.

tained from a Picker 4-circle card controlled diffractometer. Photographic measurements of the native protein intensities were used between 5 Å and 2.8 Å. These films, obtained by an extension of the scheme described previously²⁴, were scanned on a semi-automatic Joyce Loebel micro-densitometer and absorbance values along each row of reflections were punched on paper tape. Data for heavy atom derivatives, for all terms visible on the native films, were measured on a 4-circle diffractometer. Two Friedel opposites were measured for data to 3.0 Å resolution, and four equivalent reflections, two of type $hk\lambda$ and two of type hkl , were registered between 3.0 Å and 2.8 Å resolution. Integrated intensity values for all reflections in a film plane were computed from the measured absorbances and these L_p corrected sets of data were scaled together in a standard manner²⁷. The diffractometer data were handled as described²⁴ previously with sets of data scaled together with the function

$$F_{\text{scaled}} = b F' - \frac{c}{F'}, \text{ where } F' = F_{\text{meas}} \exp - \frac{B \sin^2 \theta}{\lambda^2}$$

F is a structure amplitude and b and B are scaling parameters. The film set was scaled to the diffractometer sets by the function

$$F_{\text{scaled}} = b F' + \frac{c}{F'}$$

where the term c/F' allows for a constant systematic error on the estimation of the background correction for film intensities.

Refinement of heavy atom parameters and phase angle calculations were carried out as already described²⁴. Heavy atom occupancies of different groups of crystals were refined independently. A somewhat arbitrary weighting function, incorporating the estimated errors for individual reflexions, was used in the phase angle calculation and the refinement. Anomalous dispersion measurements were included in the phase determination, the ratio of the anomalous to real scattering factors being determined as a function of $\sin \theta$ (Fig. 1) for each derivative.

The heavy atom parameters are shown in Table 1 and the mean F and lack of closure errors for all derivatives in Table 2. Fig. 2 shows the distribution of the figure of merit, the calculated heavy atom contribution f_H , and the RMS lack of closure E , with $\sin \theta$ for MMN (the best derivative) and BDM (the poorest).

The "best" Fourier synthesis²⁸ was calculated for 7,650 independent reflexions in sections perpendicular to c at intervals $a/160$, $b/160$, $c/160$ corresponding to 0.92 Å intervals in a and b and 0.97 Å in c . A modified version of a contouring subroutine (written by Zisk and Brenner at MIT) was used to produce points of equal electron density which were joined by spline-like curves²⁹ to produce contoured sections. These sections were drawn on a Calcomp plotter, photographed and redrawn on glass at the scale of 2 cm = 1 Å for model building using a Richards optical comparator³⁰ and Kendrew model parts (manufactured by the Cambridge Repetition Engineers).

The electron density map has been interpreted in terms of a single polypeptide chain of some 311 residues

Fig. 2. Figure of merit distribution

Fig. 3. Various indicators of error plotted as a function of $\sin \theta$ for (a) the best (MMN) and (b) the poorest (BDM) compound.

whereas the most recent amino-acid analysis suggests approximately 326 residues²². Because a complete amino-acid sequence is not yet available and the electron density distribution at 2.8 Å does not allow unambiguous distinction between different amino-acids, the side chains were fitted only as far as their β carbons, except for the eighteen residues at the amino end, thirteen in the essential thiol peptide and two at the carboxyl end. Fig. 4, map sections 30 to 40/160c, illustrates the fit of the electron density to the polypeptide backbone in the region of the anti-parallel ribbon, as well as the known residues near the amino terminus. The contrast between solvent and protein was found to be excellent. There is only one major uncertainty of chain folding, and this occurs about twenty residues from the N-terminus, where the density used is very close to a 2-fold axis and either of two junctions may be made.

The Molecule of Lactate Dehydrogenase

The conformation of the lactate dehydrogenase subunit, viewed from the molecular centre looking down c , is illustrated in Fig. 5. Features of secondary and tertiary structure, including the nomenclature used in the text, are summarized in Table 3. About 24 per cent of the residues are in α -helical conformation and a further 10–15 per cent in β structure, the latter being a well defined parallel pleated sheet resembling that found in subtilisin³¹ and less well defined anti-parallel pleated ribbon. A further sixteen residues are involved in single

turns of 3_{10} helix. Except for twenty residues at the N-terminus, the subunit is globular; it may be viewed as two halves separated by a considerable cleft with three connecting chains. The left hand portion, consisting principally of the N-terminal 130 residues, has the greater proportion of regular secondary structure. It contains four α helices (42 residues) and a stretch of parallel pleated sheet (23 residues). The adenine end of the coenzyme binding site is within this part of the subunit; the nicotinamide end is within the cleft. The right half, with less obvious secondary structure, contains the "essential thiol peptide" which also borders the cleft. Residues 194-209 form a winglike feature which is a part of the boundary of the right half with solvent. At the front of the subunit the two halves are joined by an imperfect anti-parallel pleated ribbon which also forms the subunit boundary. Helix H (289-300), slightly separated from the rest of the subunit, is close to the C terminus. The last eight residues are an extended chain with density consistent with a phenylalanine at the end.

The two possible positions of the N-terminal 20 residues relative to two monomers are shown in Fig. 6. Residues 1-18 occupy symmetry equivalent electron density in either interpretation. The proposed sequence for these residues²² fits the density adequately. The preferred orientation has been chosen in spite of its unusual conformation because the electron density distribution is more continuous. These alternatives have interesting implications. In the position preferred, residues 1-18 of the first subunit interact with a second subunit formed by rotation about the 2-fold axis parallel to c . The helix A wraps around the far side of the second subunit. The less preferred interpretation involves residues 7-18 folding back over the first subunit; helix A then projects in front of the rest of the subunit and is in contact with a third subunit formed by rotation of the first about the 2-fold axis parallel to a . The preferred orientation involves many more contacts between subunits. These seem to be both hydrogen bonding and hydrophobic interactions, but in the absence of a complete sequence, no more detailed interpretation of these contacts can be made.

Residues 22-26 form the central strand of the parallel pleated sheet; the chain then passes beneath the sheet forming a nine residue helix B (32-40) to the second strand (45-48) and beneath again through helix C (55-72). The chain then passes above the sheet and a fourth strand forms next to the central one (78-86). A loop

Fig. 4. Stereo view of LDH skeletal model optically superimposed on sections $z=30$ to $40/160c$, showing the fit of the electron density to the polypeptide backbone (in centre) and known amino-acid residues (at top).

across the back of the subunit, including helix D (95–106), (12 residues) forms a lip of the central cleft. Helix D (10 residues, 109–118) above the sheet, follows immediately and the fifth strand of sheet (121–123) next to the cleft is then formed. The hydrogen bonding within the sheet is shown in Fig. 7. Residues immediately following the three central strands of the sheet are involved in contacts to the adenine, adenine ribose, phosphates and nicotinamide ribose, while the C-terminal residue of helix D is in contact with the adenine (Fig. 8). Caution should be observed, however, in considering which residues are involved in coenzyme binding, for the reduc-

tion in crystal symmetry and probable conformation change occurs when any fragment of the dinucleotide larger than adenosine is diffused into the crystals.^{11,24}

The "essential thiol peptide" has been identified because residue 149 is the ligand for the B site of mercury substitution in the HgCl₂ and MMN derivatives^{24,25}. The known sequence of this peptide has been fitted to the electron density satisfactorily and its conformation is shown in Fig. 9. It bounds the central cleft opposite the coenzyme binding site. The sulphydryl is separated from the cavity by this part of the main chain, but both serine 147 and asparagine 150 point into the cavity

Fig. 5. α -Carbon positions for one subunit viewed along c from the molecular centre, with preferred positions of N-terminal residues.

Fig. 7. Five-stranded parallel sheet and coenzyme. β -Carbon positions and hydrogen bonding of sheet are indicated.

above and below the nicotinamide and about 6 Å away. The main chain again approaches the central cleft at residue 181. It is interesting that the essential thiol of pig glyceraldehyde 3-phosphate dehydrogenase is 149 and the essential lysine is 183^{32,33}. A chain conformation similar to that of dogfish M₁ LDH would enable an active centre including these residues to be formed.

The central cleft is shown in Fig. 8. Its opening to solvent is made by the loop (86-109) joining the fourth strand of parallel sheet and helix E. A comparison of the apo-enzyme and the abortive ternary complex at 5 Å resolution (Fig. 10) shows the major difference between them to be the conformation in this region. In the ternary complex the loop moves about 12 Å so as to close the

entrance to the cleft and covers the nicotinamide end of the coenzyme. A rather isolated peak found in the 5 Å map of the apo-enzyme and interpreted as a solvent ion in the 2.8 Å map, is considerably enlarged in the 5 Å map of the abortive ternary complex. This peak is near asparagine-150, serine-147, and the nicotinamide of the coenzyme. Whether this represents a substrate binding site might be resolved when a high resolution map of the ternary complex has been calculated.

The parts of the subunit which form boundaries may be noted, although it is difficult to make a detailed analysis of contacts in the absence of a complete sequence. Subunits related by the 2-fold axis parallel to *c* have the helices C, B, and G of one in contact with G, B, and C

Fig. 8. View from molecular boundary showing the coenzyme and central cavity.

Fig. 9. Arrangement of thirteen residues of the "essential thiol" peptide and their spatial relationship to the nicotinamide end of the coenzyme.

Fig. 10. The 5.0 Å electron density models of the abortive ternary complex (left) and the apo-enzyme with the coenzyme placed into it (right). The coenzyme is shaded.

of the other, respectively. The N-terminal helix A makes contacts with the winglike feature of the subunit related to it by the molecular axis parallel to *c*. The subunits related by the axes parallel to *a* and *b* have in contact mainly the anti-parallel pleated sheet and some random coil at residues 160–170. Close to these residues all four subunits are in contact. The coenzyme binding site and the region expected to bind substrate are both wholly within one subunit. The closest approach between adjacent coenzymes is 19 Å, while the nicotinamide ends are as much as 26 Å apart. The elucidation of the structure of the enzyme-coenzyme complex and of the abortive ternary complex may throw light on the importance of a tetrameric molecule.

We thank Professor N. O. Kaplan for several gifts of enzyme, Dr H. L. Mermall for enzyme preparations and crystallization, Drs R. Leberman, P. Wasserman, and J. Birktoft for discussion, members of Purdue University's Computer Center for cooperation, and Mrs J. Jacobson, Mrs F. Struble, Mrs E. Pollock, Mrs J. Erdmann, Mrs M. Ginsky, Mrs D. A. Gomez, and Mrs M. Wonacott for technical assistance. This work was supported by grants from the US National Institutes of Health, the US National Science Foundation, and to a lesser extent by Eli Lilly and Company. Samples of the Baker dimercurial were supplied by the Cancer Chemotherapy National Service Center.

Mechanism of Pyruvate Carboxylase Formation from the Apo-Enzyme and Biotin in a Thermophilic Bacillus

by

Leicester, LE1 7 RH

Pyruvate carboxylase is formed by enzyme-catalysed attachment of biotin to an inactive protein precursor. Acetyl-CoA and aspartate allosterically influence this reaction.

THE enzyme pyruvate carboxylase is synthesized by the addition of biotin to its inactive protein precursor, apo-pyruvate carboxylase. This reaction is catalysed by holoenzyme synthetase. When grown without a supply of biotin, a strain of thermophilic bacillus synthesizes large amounts both of the inactive apo-pyruvate carboxylase and of the holoenzyme synthetase. Pyruvate carboxylase activity appears rapidly when biotin is added to these cells, in the absence of protein synthesis. The reconstitution of the enzyme activity in cell-free extracts demands acetyl-CoA as well as Mg^{2+} , biotin and ATP¹. Neither the need for acetyl-CoA, nor the effect of L-aspartate in antagonizing its action, has been observed with other carboxylating systems^{2–9}.

The apo-enzyme can be purified from cultures of the bacillus, (a starch-negative variant of *Bacillus stearothermophilus*¹⁰, previously referred to as *B. coagulans* sp.¹), which have been grown on succinate medium, by a procedure similar to that described¹¹ for the purification of the active pyruvate carboxylase. This involves growth of the organism¹² at 55° C, preparation of extracts of the washed cells by digestion with lysozyme, and repeated

fractionation with ammonium sulphate. A fraction containing both the apo-enzyme and the holoenzyme synthetase can then be resolved into the two protein components by chromatography on 'Sephadex G-200' as illustrated by the elution profiles of Fig. 1, which demonstrate that the apo-enzyme is eluted well before the holoenzyme synthetase. This experiment was designed primarily to demonstrate the effect of acetyl-CoA on the incorporation of ¹⁴C-biotin into the apo-enzyme. When acetyl-CoA was not included in the incubation mixture, there was very little incorporation of (+)-¹⁴C biotin into the apo-protein and virtually no formation of pyruvate carboxylase activity (Fig. 1a). When the experiment was repeated with the sole difference that 2.5 μmoles of acetyl-CoA were also included in the incubation mixture, the results obtained were markedly different. Thus Fig. 1b shows a large peak of radioactivity associated with a protein, which possessed pyruvate carboxylase activity, was eluted at the same place as that occupied in Fig. 1a by the apo-protein, and was well separated from the synthetase. Clearly, the inclusion of acetyl-CoA in the incubation system leads to the reconstitution of the active

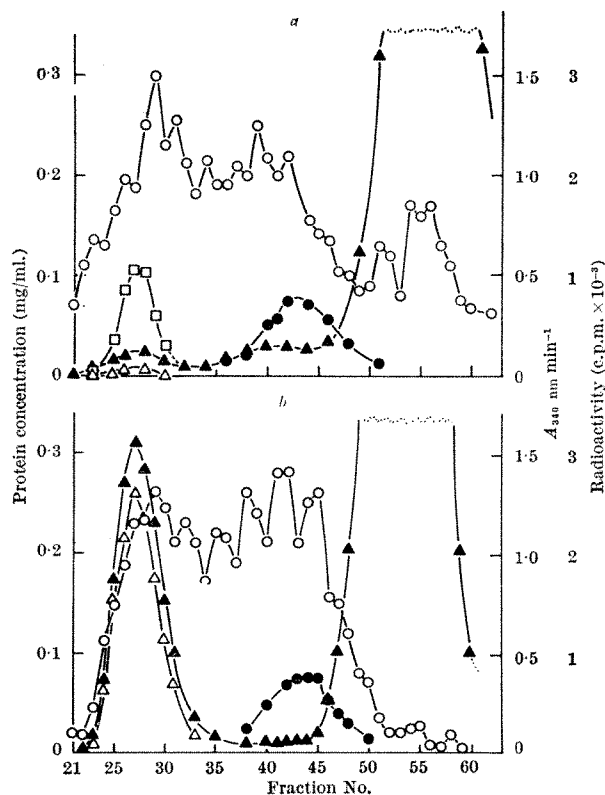

Fig. 1. *a*, Requirement for acetyl-coenzyme A in the formation of active pyruvate carboxylase from the apo-enzyme and ^{14}C -biotin. The purified apo-protein (2.2 mg) and holoenzyme synthetase (3.1 mg) obtained after 'Sephadex G-200' chromatography were mixed with 12.5 μmoles of MgCl_2 , 3.1 μmoles of ATP, 0.17 μmoles of (+)- ^{14}C -biotin (containing 10 μCi of isotope) and 37.5 μmoles of Tris-HCl buffer (pH 7.6), in a final volume of 7 ml. The mixture was incubated for 30 min at 45°C , cooled to 0°C , 20 μmoles of EDTA were added and the proteins were precipitated with 20 ml of saturated ammonium sulphate. The precipitate was dissolved in 0.5 ml of 50 mM-Tris-HCl buffer (pH 7.6), containing 1 mM EDTA and 0.4 M ammonium sulphate, and the solution was applied to a column of 'Sephadex G-200' (1.7 \times 30 cm) equilibrated with this buffer; the proteins were then eluted with the same buffer. Fractions of 1 ml. were collected and assayed for protein, radioactivity, and the activities of pyruvate carboxylase, the apo-enzyme, and holoenzyme synthetase. Protein (O) was determined spectrophotometrically¹³ and radioactivity (Δ) was measured in a Tracerlab scintillation spectrometer after mixing samples (0.5 ml.) with 5 ml. of Bray's fluid¹⁴. Holoenzyme synthetase (●) was assayed spectrophotometrically¹. For the assay of apopyruvate carboxylase (□) or holoenzyme synthetase (●) the sample was incubated in a mixture (0.3 ml.) containing (in μmoles) Tris-HCl (pH 7.6), 15; MgCl_2 , 0.5; acetyl-coenzyme A, 0.1; (+)-biotin, 0.07, and an excess of synthetase or apo-enzyme as appropriate. After incubation at 45°C for 15 min, the reaction was stopped by placing the tubes in an ice bath and adding 1 μmole of EDTA. Portions (0.2 ml.) of these mixtures were withdrawn and the holoenzyme synthetase formed was determined spectrophotometrically¹ by measuring the rate of decrease in extinction at 340 nm concomitant with the oxidation of NADH, in the presence of malate dehydrogenase, by the oxaloacetate synthesized in the pyruvate carboxylase reaction. One unit of apopyruvate carboxylase is defined as that amount of the apo-enzyme which, on total conversion, yields one unit of holoenzyme, which catalyses the formation of one μmole of oxaloacetate per min at the temperature of assay (45°C). One unit of synthetase is defined as that amount of the enzyme which catalyses the conversion of one unit of the apo-enzyme to the holoenzyme per min at 45°C . *b*, Protein (O), radioactivity (Δ), holoenzyme synthetase (●) and holoenzyme synthetase (●) were assayed as in *a*. Conditions were as in *a* except that 2.5 μmoles of acetyl-CoA were included in the initial incubation mixture.

enzyme from the apo-protein, and to the attachment of biotin to that protein.

As shown in Table 1, this reconstitution reaction required the two protein components (apo-enzyme and synthetase), a divalent cation (Mg^{2+} or Mn^{2+}), (+)-biotin, ATP and acetyl-CoA. In this system, with an excess of apo-carboxylase, formation of active enzyme was linear with respect to time of incubation (15–20 min) and to the amount of synthetase protein. With an excess of synthetase protein and an appropriate incubation period (15 min), the formation of active enzyme was proportional to the amounts of apo-enzyme added. Acetyl-CoA was required for pyruvate carboxylase formation even at 30°C , at which temperature both the

apo-enzyme and the holoenzyme synthetase were completely stable for the times of incubation used. This suggests that acetyl-CoA acts as an allosteric effector of the reconstitution process rather than as a stabilizing agent for one or other of the protein components of the reaction system.

Fig. 2. Replacement of (+)-biotin, ATP and MgCl_2 by biotinyl-AMP for the formation of pyruvate carboxylase. The reaction mixture with biotin-ATP- MgCl_2 (●) was as described in the legend to Fig. 1a, for the assay of apopyruvate carboxylase and holoenzyme synthetase, with 0.35 mg of apopyruvate carboxylase and 0.41 mg of synthetase. The reaction mixture with biotinyl-AMP (Δ) contained (in μmoles) in a final volume of 0.3 ml.: Tris-HCl buffer (pH 7.6) 15; acetyl-CoA, 0.1; biotinyl-AMP, 0.067; and apopyruvate carboxylase and synthetase as above. Following incubation at 45°C as indicated, the holoenzyme synthetase formed was determined.

Fig. 3. Effect of acetyl-CoA and L-aspartate on the synthesis of holoenzyme synthetase. *a*, Holoenzyme synthesized at different L-aspartate concentrations with a fixed concentration of acetyl-CoA (75 μM) was measured in the reaction systems described in the legend to Fig. 1 and expressed as per cent of the active enzyme formed in the absence of L-aspartate. In the absence of L-aspartate, the amount of active enzyme formed was 0.155 unit with biotin-ATP- MgCl_2 , and 0.092 unit with biotinyl-AMP. ●, (+)-biotin-ATP- MgCl_2 system; Δ, biotinyl-AMP system. *b*, Holoenzyme synthesized at different acetyl-CoA concentrations and at a fixed concentration of L-aspartate (10 mM) was determined and expressed as per cent active enzyme formed at an acetyl-CoA concentration of 75 mM in the absence of L-aspartate. The 100 per cent values were 0.191 unit of holoenzyme for the system with biotin-ATP- MgCl_2 , and 0.095 unit for the system with biotinyl-AMP. ●, (+)-biotin-ATP- MgCl_2 system; Δ, biotinyl-AMP system.

Table 1. REQUIREMENTS FOR HOLOPYRUVATE CARBOXYLASE SYNTHESIS FROM BIOTIN AND ATP

	Pyruvate carboxylase synthesized (per cent of complete)
Complete	100
Reduced glutathione (1 μ mole) added	91
MgCl ₂ omitted	15
MgCl ₂ omitted; MnCl ₂ (0.5 μ mole) added	92
Acetyl-coenzyme A omitted	9
Biotin omitted	0
ATP omitted	9
Apopyruvate carboxylase omitted	0
Synthetase omitted	0

The complete system was the one described in legend to Fig. 1; 64 μ g of apopyruvate carboxylase and 78 μ g of synthetase were used. Additions and omissions were made as indicated. The amount of pyruvate carboxylase synthesized in the complete system (taken as 100 per cent) was 0.168 unit.

Pyruvate carboxylase was reconstituted also in mixtures of the purified apo-enzyme and holoenzyme synthetase when synthetic (+)-biotinyl-5'-AMP (biotinyladenylate) was used in place of biotin and ATP: the adenylate derivative was almost as efficient as (+)-biotin and ATP in this process (Fig. 2). Again, the active enzyme was formed only if both protein components, biotinyl-AMP and acetyl-CoA were present; in the absence of acetyl-CoA, the yield of active enzyme was reduced by 94 per cent. Unlike the system described in Table 1, Mg²⁺ was not required for the formation of pyruvate carboxylase when biotinyl-AMP was the biotin donor, and EDTA did not inhibit the reaction.

An inhibitory action of L-aspartate on the synthesis of active enzyme, was demonstrated in our earlier studies with crude extracts¹. This has now been observed also in the purified, resolved system. Fig. 3 shows the effect of L-aspartate (a) or acetyl-CoA (b) on the formation of active enzyme. In either case, the effect was similar whether biotinyladenylate, or biotin and ATP were supplied. The two sets of curves show the mutual antagonism between acetyl-CoA and L-aspartate and their pronounced sigmoidicity suggests strongly that these compounds are exerting an allosteric effect on the formation of pyruvate carboxylase.

The resolution of the pyruvate carboxylase reconstitution system into the apo-enzyme and the holoenzyme synthetase, and the efficiency with which biotinyladenylate substitutes for biotin and ATP in it, underline the similarity of the mechanisms of synthesis of biotin-dependent carboxylases from their apo-enzymes and biotin. Formation of active propionyl-coenzyme A carboxylase⁴, methylmalonyl-coenzyme A-oxaloacetate trans-

carboxylase⁵ and acetyl-coenzyme A carboxylase⁶ takes place in two steps, catalysed by holoenzyme synthetases that are not species specific. By analogy, the synthesis of active pyruvate carboxylase in our system can be represented as

The target of action of acetyl-CoA in this sequence of reactions is not certain. Although experiments with biotinyladenylate prove that acetyl-CoA is essential for the second step, the effect could be on either the apo-carboxylase or on the synthetase, or both. Because acetyl-CoA is required for the activity of the holoenzyme¹², the apoprotein is the most likely point of action of the activator; but we cannot yet rule out a possible effect of acetyl-CoA on the synthetase that effects both the synthesis of biotinyl-5'-AMP and its reaction with the apo-enzyme.

We thank Miss Susan N. Dिल्s for technical assistance, Professor M. F. Utter for discussion and Mr G. Asquith for preparing the figures. This work was performed during the tenure by J. J. C. of a postdoctoral fellowship of the Consejo Nacional de Investigaciones Científicas y Técnicas (Republica Argentina) and was supported by the Science Research Council.

Control of Synthesis and Wastage of Ribosomal RNA in Lymphocytes

by

HERBERT L. COOPER

Cell Biology Section,
National Institute of Dental Research,
National Institutes of Health,
Bethesda, Maryland 20014

Phytohaemagglutinin stimulates the synthesis of the 45S ribosomal precursor in lymphocytes without concomitant protein synthesis; it also decreases the loss of newly synthesized 18S RNA that normally takes place in these cells at rest.

STIMULATION of RNA synthesis in human lymphocytes by phytohaemagglutinin (PHA)¹⁻⁴ causes an increase in the synthesis of 45S RNA which is disproportionately large relative to the stimulation of overall RNA synthesis². We have shown that, in the resting lymphocyte, approximately half of the newly synthesized 18S rRNA molecules are rapidly degraded, apparently without ever entering the cytoplasm^{5,6}. This is detected by a disparity in the labelling ratio between 28S and 18S rRNAs, which should be synthesized, and labelled, in equimolar amounts

according to our present understanding of the mode of synthesis of rRNA. Both forms of rRNA derive from a single 45S precursor molecule, implying coordinate production of the two forms⁷⁻¹⁰. The excess new 28S rRNA molecules remaining after rapid degradation of 18S rRNA are also degraded, but only after a lag period, thereby permitting the detection of the early loss of 18S molecules⁶. The wastage of rRNA seen in resting lymphocytes is promptly reduced by PHA⁶.

Thus PHA seems to act in at least two different ways

Fig. 1. Early effect of PHA on 45S RNA synthesis. 5×10^7 lymphocytes were incubated in Eagle's minimal essential medium, deficient in methionine, at a density of 2×10^6 /ml. [$\text{methyl-}^3\text{H}$]Methionine (20 $\mu\text{Ci}/\text{ml}$, 4.7 Ci/mmol, Schwarz Biosearch) was added for a 1 h labelling period. RNA was then extracted with phenol-sodium dodecyl sulphate at 40°C (ref. 12) and sedimented on sucrose gradients (8–25 per cent) for 17 h at 22,000 r.p.m. (Spinco 'SW-41' rotor). Serial gradient fractions were collected from the bottom of the tube and acid insoluble radioactivity in each fraction was determined. Absorbance markers were provided by rRNA extracted from rat liver and added during the extraction procedure (arrows). Direction of sedimentation is right to left. A, Resting lymphocytes; B, PHA (2.5 $\mu\text{g}/\text{ml}$, Burroughs-Wellcome) added 1.5 h before labelling.

to provide the stimulated lymphocyte with the means of increasing rRNA production: by increasing initial synthesis, and by reducing wastage of newly produced molecules. It is not clear, however, whether these effects are independent actions of PHA on different biochemical events, or are interdependent effects, one occurring as a consequence of the other. I have now resolved these phenomena, which I conclude to be independent of one another and to have different biochemical characteristics.

Human peripheral blood lymphocytes were used in these experiments¹¹. Newly synthesized rRNA was labelled with ^3H -methyl groups from [$\text{methyl-}^3\text{H}$]methionine⁶ and extracted with phenol and sodium dodecyl sulphate¹². Heterogeneous forms of RNA are not labelled by this procedure, whereas rRNA is specifically labelled^{13–15}.

The early stimulation of 45S RNA synthesis by PHA has been demonstrated previously using ^3H -uridine labelling². In Fig. 1 this stimulation is confirmed using [$\text{methyl-}^3\text{H}$]methionine as a precursor. Pre-treatment of resting lymphocytes with cycloheximide, in a dose which eliminated 98 per cent of protein synthesis, caused a fall in the rate of 45S synthesis, but subsequent addition of PHA still produced a rise in 45S RNA labelling (Fig. 2). This was not detectable in earlier studies using ^3H -uridine labelling because of interference by the large amount of radioactivity entering heterogeneous forms of RNA². It is evident, however, that synthesis of 45S RNA may be increased, to some extent, without a requirement for new protein synthesis.

Several investigators, using various eukaryotic systems, have reported that abolition of protein synthesis with cycloheximide results in a marked fall in production of new 18S rRNA molecules^{9,16–19}. This is apparently the result of the rapid degradation of newly formed 18S molecules when concomitant protein synthesis

is prevented. We have observed the same effect in lymphocytes, both resting and growing, and in Burkitt lymphoma cells. This effect is illustrated as follows (Fig. 3B, D).

The untreated, resting lymphocyte, in a very similar manner, has been shown to degrade a large portion of its newly synthesized 18S rRNA^{5,6}. This is illustrated in Fig. 3A, where the ratio between radioactivity incorporated into 28S and 18S rRNAs during a 2 h pulse is 3.8. Equimolar production of 28S and 18S rRNAs, which is anticipated from the mode of rRNA synthesis, would give a 28S : 18S labelling ratio of 1.4–1.5, based on the molecular weights of the two forms and their characteristic degrees of methylation³. The observed 28S : 18S ratio implies the loss of more than 60 per cent of newly synthesized 18S rRNA molecules. Treatment of the cells with cycloheximide, before labelling, results in an even greater 28S : 18S disparity, implying still greater degradation of newly synthesized 18S rRNA (Fig. 3B). Addition of PHA to resting lymphocytes 2 h before labelling produced a prompt reduction in the wastage of 18S rRNA (Fig. 3C), the 28S : 18S labelling ratio falling to 1.75 (18S wastage = 18 per cent). Treatment with cycloheximide before addition of PHA prevented this increased 18S rRNA production (Fig. 3D). In the latter conditions, however, 45S RNA synthesis was stimulated. Clearly, therefore, the increase in 45S RNA synthesis which follows PHA treatment is not a consequence of reduced wastage of rRNA.

It is apparent from the effect of cycloheximide treatment that continuous protein synthesis is required for survival of new 18S rRNA (Fig. 3B,D)^{9,16,19}. This requirement was studied further to determine which step in 18S rRNA production may be sensitive to abolition of protein synthesis. The 45S rRNA precursor was labelled with [$\text{methyl-}^3\text{H}$]methionine during a 50 min pulse in resting lymphocytes. A 1 h chase was then performed, in the presence of a high dose of actinomycin D, in various conditions, and the 18S rRNA deficit calculated (Table 1).

The presence of cycloheximide during both the pulse and chase periods caused an increase in the normally high degree of 18S rRNA wastage in resting cells. If, however, protein synthesis was permitted to proceed normally during the pulse but was abolished by addition of cycloheximide during the chase, no increase in wastage occurred. It may be concluded that the availability of newly synthesized proteins during 45S RNA synthesis is sufficient to protect the 18S portion of about half of

Fig. 2. Stimulation of 45S RNA synthesis by PHA in the absence of protein synthesis. Lymphocytes were incubated and labelled, after which RNA was extracted, as in Fig. 1. A, Resting cells; B, cycloheximide, 25 $\mu\text{g}/\text{ml}$, added 1 h before labelling; C, cycloheximide added 2.5 h before labelling; PHA added 1.5 h before labelling.

Table 1. WASTAGE OF 18S rRNA IN LYMPHOCYTES
50 minute pulse, 1 hour chase

Pulse	Additions to: Chase	Percentage 18S rRNA deficit
1. —	AMD	40
2. CHx	CHx+AMD	70
3. —	CHx+AMD	32
4. —	PHA+AMD	21
5. —	PHA+CHx+AMD	40

Results of a 50 min pulse, 1 h chase. Resting lymphocytes were incubated with [*methyl-³H*]methionine for 50 min (ref. 5). Medium was replaced with fresh medium containing excess unlabelled methionine and the additions shown. After 1 h RNA was extracted with phenol-sodium dodecyl sulphate at 40° C and sedimented through sucrose gradients¹². Distribution of radioactivity in 28S-32S and 18S peaks was determined as in Figs. 1-3 and the 28S : 18S labelling ratio calculated. On the basis of an expected 28S : 18S labelling ratio of 1.45 the percentage 18S rRNA deficit was calculated². Actinomycin D was used at a concentration of 10 µg/ml.

the new 45S molecules from subsequent degradation on cessation of protein synthesis. As little as 5 min is required in resting cells to abolish protein synthesis with the doses of cycloheximide used (unpublished). It is unlikely, therefore, that there was enough residual protein synthesis after addition of cycloheximide to explain the failure of the drug to increase 18S rRNA degradation when added only during the chase.

When PHA was added during the chase period, the normally high wastage of the 18S portion of previously synthesized 45S RNA was markedly reduced. A similar result has been observed, independently, by A. D. Rubin (personal communication). I observed this effect in the presence of a high dose of actinomycin, which has been shown to reduce lymphocyte RNA synthesis, almost immediately¹¹, to about 2 per cent of control levels (personal communication from R. Stern). But addition of cycloheximide together with PHA completely prevented this effect.

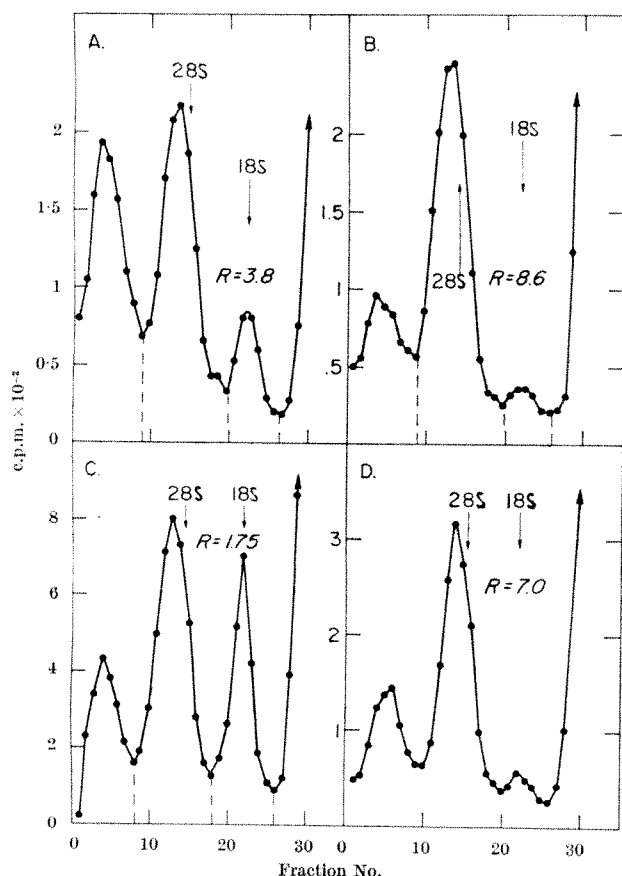

Fig. 3. Effect of PHA and cycloheximide on labelling of 18S rRNA. Lymphocytes were labelled with [*methyl-³H*]methionine for 2 h. Conditions otherwise as in Fig. 1. A, Resting cells; B, cycloheximide added 30 min before labelling; C, PHA added 2 h before labelling; D, cycloheximide added 2-5 h before labelling; PHA added 2 h before labelling. R designates ratio: (c.p.m. in 28S+32S)/(c.p.m. in 18S).

It seems that PHA can act very promptly to prevent degradation of a large portion of those 18S molecules synthesized in resting lymphocytes which would normally have been wasted. This action requires continuous protein synthesis, but does not require RNA synthesis. Thus both the normal survival of 18S rRNA, seen in resting cells, and the increased survival produced by PHA, are dependent on protein synthesis. Because, as noted, the rapid loss of new 18S rRNA molecules is accompanied by an equivalent but delayed loss of new 28S molecules, the availability of the required protein may set an upper limit on the rate of accumulation of new ribosomes. This may be an important growth regulating mechanism, for normal lymphocyte growth and division do not occur when ribosome production is blocked²⁰.

The action of PHA in reducing 18S rRNA wastage is independent of the PHA-induced rise in 45S RNA synthesis, for the former effect was observed in the presence of actinomycin. Further, the decrease of rRNA wastage requires intact protein synthesis, whereas increase of 45S RNA synthesis does not. Thus the two effects of PHA on rRNA metabolism seem to be independent and have different biochemical characteristics. Thus if a single primary PHA-induced event exists, it sets in motion more than one secondary series of events.

The findings have broader implications for the understanding of the control of gene action in animal cells. Thus 45S RNA is a primary gene product, albeit of a highly specialized nature. Although specialized processes have evolved to regulate its synthesis and utilization, it is also probable that certain basic steps are common to the handling of 45S RNA and the more elusive mRNA of the animal cell. The two steps examined here in regard to rRNA processing may have counterparts in the metabolism of mRNA. It is therefore likely that control at the transcriptional level exists for mRNA in animal cells, as it seems to exist for 45S RNA. More speculative, but highly intriguing, is the possibility that for mRNA, as for rRNA, a mechanism exists which determines the survival or degradation of newly synthesized mRNAs. This possibility has been raised by a number of workers²¹⁻²³. The large amount of heterogeneous, high molecular weight, labile RNA produced in the nuclei of all animal cells studied (reviewed in ref. 11), may include a pool of messages of which only those which are protected from immediate degradation will survive and be used. Whether such protection of mRNA is specific or non-specific, how it is mediated, indeed whether it exists at all, are questions for further study. The means by which new rRNA is protected from rapid degradation may serve as a starting point.

Mutations affecting the Size of the Nucleolus in *Xenopus laevis*

by

LEO MILLER
J. B. GURDONDepartment of Zoology,
Parks Road, Oxford

In *Xenopus laevis*, nucleolar mutants which form a partial nucleolus have been isolated. These provide a unique opportunity for the genetic analysis of the very reiterated ribosomal RNA genes.

THE nucleolus has always occupied an important place in the study of cell growth and protein synthesis, but its precise role was greatly clarified when it was shown to be the cellular organelle responsible for the synthesis of ribosomal RNA. The nucleolar organizer, which McClintock¹ defined as the chromosomal site necessary for the orderly organization of the nucleolus, is now known to be the location of the very reiterated ribosomal RNA genes^{2,3}.

The ribosomal RNA genes represent one of the few classes of reiterated genes for which a function is established, but it is not known if they are identical or how many are needed to permit the normal rate of ribosomal RNA synthesis and hence normal development. A detailed answer to these questions requires a particular class of mutants—one in which the normal number of ribosomal RNA genes has been reduced by deletion.

The ribosomal RNA genes are unique in that their rate of transcription and their distribution between the nucleolar organizers can be judged by cytological criteria⁴⁻⁷. More specifically, the relative abundance of ribosomal RNA genes in the two nucleolar organizers of a nucleus is reflected by the relative size of the two nucleoli⁷. We might therefore expect to be able to select the desired ribosomal gene mutants by the cytological analysis of nucleoli. *Xenopus* is particularly suitable for this type of work because large numbers of individuals can be cytologically analysed by examining a few cells from the tail tips of tadpoles which can then be reared to form a stock for genetic analysis. In this communication we outline the use of this approach to isolate partial nucleolar mutants and describe their origin, inheritance, cytological characteristics and development.

Characteristics of Partial Nucleolar Variants

The class of mutants in which we are interested would be expected to appear in heterozygous form as individuals with a large nucleolus (formed by a normal nucleolar organizer) and a partial nucleolus (formed by an organizer with a partial deletion of ribosomal RNA genes). We refer to this general class of nucleolar variants, having unequal sized nucleoli in most cells, as $+/p\ nu$. They are clearly distinguishable from wild type individuals which have two equal sized nucleoli ($+/+ \ nu$) in most cells (Fig. 1a and b). We can also recognize, within the $+/p\ nu$ variants, a category referred to as $+/p^1\ nu$. These are distinguished by the presence of extremely unequal sized nucleoli (Fig. 1c) and (as described later) by the lethality of the $0/p^1\ nu$ hemizygotes.

Table 1. NUCLEOLAR CONDITION OF PROGENY FROM SEVENTEEN CROSSES BETWEEN INDIVIDUALS HAVING TWO EQUAL NUCLEOLI

Nucleolar condition	Number of progeny*	Percentage
Two equal nucleoli ($+/+ \ nu$)	720	96.3
Two unequal nucleoli ($+/p\ nu$)	25	3.3
One nucleolus ($+/0 \ nu$)	3	0.4

* All of the progeny analysed were $+/+ \ nu$ in eight of the seventeen crosses and the $+/p\ nu$ embryos were found in the remaining nine crosses. Thirty-five embryos from each of the crosses were analysed.

To identify $p\ nu$ variants we have removed the tail tips of tadpoles at Nieuwkoop and Faber⁸ stage 32-42 for the examination of squash preparations by phase contrast microscopy. Nucleolar variants have been found among the progeny of frogs imported from Africa as well as among those of X-rayed frogs. Altogether, forty-one imported frogs have been analysed and five (12 per cent) produced progeny of which about half had slightly unequal nucleoli (Fig. 1b) when mated with $+/+ \ nu$ individuals. Thus these five frogs are probably heterozygous for an altered nucleolar organizer which forms only a partial nucleolus ($+/p\ nu$). This finding is consistent with the report that some individuals in natural populations of *Bufo marinus*⁷ and *Xenopus laevis*⁹ have unequal sized nucleoli or unequal nucleolar organizer constrictions¹⁰.

In the hope of increasing the frequency and severity of the $p\ nu$ variants, three male *Xenopus* were exposed to 1,200 rads of X-irradiation and mated within 3 days. Most of the progeny had a normal nucleolar constitution but a few variants were found with extremely unequal nucleoli. These $+/p^1\ nu$ variants (Fig. 1c) develop normally and are indistinguishable in viability from $+/+ \ nu$ animals.

The occasional origin of $p\ nu$ variants from crosses of two normal $+/+ \ nu$ parents has also been observed. The results of these crosses (Table 1) show that about half of the seventeen crosses between $+/+ \ nu$ frogs yielded some nucleolar variants, including some tadpoles with extremely unequal nucleoli, and three tadpoles with only one nucleolus per nucleus. These three tadpoles with one nucleolus per cell ($+/0 \ nu$, formerly known as 1- nu), have developed and metamorphosed normally, and represent the first reported cases of $+/0 \ nu$ frogs known to have arisen among the progeny of $+/+ \ nu$ parents. The 1- nu ($+/0 \ nu$) mutant of *Xenopus* originally described by Elsdale, Fischberg and Smith¹¹, was isolated from the normal laboratory stock. Similarly, two $+/0 \ nu$ individuals were found in a shipment of *Xenopus* from South Africa by Blackler⁹, who estimated that the frequency of these mutants in laboratory stocks taken from natural populations was about 1.5 per cent.

The presence of individuals with unequal nucleoli in our stock, and the discovery of $p\ nu$ variants among the progeny of X-rayed and normal parents, illustrate the susceptibility of the nucleolar organizer to alteration. Furthermore, the presence of $+/0 \ nu$ and $+/p\ nu$ variants among the progeny of $+/+ \ nu$ parents strongly suggests that the changes in the nucleolar organizer may take place during meiosis.

Inheritance of the $p\ nu$ Condition

To support the view that the partial nucleolar variants are the result of genetic rather than phenotypic variations, we have tested their inheritance through mitosis and meiosis. The inheritance of the $p\ nu$ condition through

mitosis was observed by comparing the nucleolar condition of cells in various tissues of the same individual. When this is done for tadpoles with slightly unequal nucleoli ($+p\ nu$) and those with very unequal nucleoli ($+p^i\ nu$), there is a limited variation among the cells of an individual; cells with equal nucleoli are rarely seen (15/100) in $+p\ nu$ tadpoles and never (0/500) in $+p^i\ nu$ tadpoles. Similarly, cells with obviously unequal nucleoli are very rarely seen (1/500) in $+p\ nu$ tadpoles.

The inheritance of the $p\ nu$ condition through meiosis has been followed in crosses between $+p\ nu$ and $+0\ nu$ frogs. In such crosses four types of progeny in equal numbers are expected if the $p\ nu$ condition segregates like a single Mendelian factor: $+/\ +\ nu$ (two equal nucleoli); $+p\ nu$ (unequal nucleoli); $+0\ nu$ (one nucleolus); and $p/0\ nu$ (one partial nucleolus). From such a cross, however, only three classes of progeny could be identified: about 25 per cent with two equal nucleoli, 25 per cent with two unequal nucleoli and 50 per cent with one nucleolus in each cell (Table 2). We assume that the nucleolar classes $+0\ nu$ and $p/0\ nu$ both appeared as tadpoles with a single large nucleolus in each nucleus. This result is expected in view of the well known ability of the nucleolar organizer genes to show dosage compensation, so that a constant amount of nucleolar material is organized irrespective of the number of organizers present^{7,12,13}. We have indeed observed that the size of the nucleolus formed by a $+ \nu$ nucleolar organizer is much greater when it shares a nucleus with a $p\ nu$ organizer than with another $+ \nu$ organizer.

Further evidence for the Mendelian inheritance of the $p\ nu$ condition comes from the analysis of twelve crosses between $+p^i\ nu$ frogs and $+0\ nu$ heterozygotes. The progeny of each cross include four classes of nucleolar conditions (Table 2). $p^i/0\ nu$ embryos have a single nucleolus in most cells, but can be distinguished from $+0\ nu$ tadpoles by the presence of some cells with 1-4 very small nucleolus-like bodies (Fig. 1d). These nucleolus-like bodies are variable in size and are similar to those found in the anucleolate mutants of *Xenopus*¹¹, *Chironomus*¹³ and *Zea mays*¹. In contrast to the anucleolate mutants, however, the extra nucleolar bodies of $p^i/0\ nu$ mutants are only found in small numbers, usually one or two per nucleus. In fixed preparations stained with methyl green and thionine¹⁴, the nucleoli and nucleolus-like bodies stain metachromatically as expected for structures containing RNA.

Table 2. NUCLEOLAR CONDITION OF PROGENY FROM CROSSES BETWEEN $+0\ nu$ AND $+p\ nu$ MUTANTS

Nucleolar condition of progeny	Cross and number of progeny	
	$+0\ nu \times +p\ nu$	$+0\ nu \times +p^i\ nu$
Two equal nucleoli ($+/\ +\ nu$)	53	101
Two unequal nucleoli ($+p\ nu$ or $+p^i\ nu$)	46	96
One nucleolus ($+0\ nu$)	101	94
One nucleolus ($p/0\ nu$ or $p^i/0\ nu$ *)		84*

* Distinguished from $+0\ nu$ by the presence of extra nucleolus-like bodies in some cells.

It is of interest to note that the $p^i\ nu$ organizer forms a single large nucleolus in many cells of the $p^i/0\ nu$ embryos. These nucleoli may not be normal, however, for they appear to have an abnormally high density when compared with normal nucleoli under the phase contrast microscope. Similar observations have been reported for the anucleolate mutant of *Xenopus*¹⁵, and it has been shown that the pseudonucleolus found in these mutants has an abnormal ultrastructure¹⁶.

We conclude from these tests that the $p\ nu$ condition is a mutation which is inherited as if it were a single Mendelian factor.

Development of $p\ nu$ Mutants

Analysis of the developmental effects of the partial nucleolar mutations has been greatly facilitated by

combining a $p\ nu$ or $p^i\ nu$ chromosome with a homologous chromosome totally lacking a nucleolar organizer. This is accomplished by crossing a $+p\ nu$ or $+p^i\ nu$ heterozygote with a $+0\ nu$ frog. The $p^i/0\ nu$ embryos, with a single large nucleolus in each cell, develop and metamorphose normally. In contrast, $p/0\ nu$ embryos, which contain extra nucleolus-like bodies in addition to a large nucleolus in some of their cells, die as tadpoles before starting to feed. Phenotypically the $p^i/0\ nu$ embryos are normal during the early stages of development but, after hatching, they become microcephalic, develop oedemata in the regions of the eyes, heart and abdomen, and at later stages their bodies become dorso-ventrally bent. They stop further development at stage 42 and die 9-12 days after fertilization when their normal sibs have reached stage 47 or 48.

The developmental abnormalities of the $p^i/0\ nu$ mutants are very similar to those of anucleolate mutants of *Xenopus*¹¹, but $p^i/0\ nu$ embryos live a few days longer. In order to rule out maternal effects as an explanation of longer survival, the relative length of survival permitted by these two lethal conditions was determined by mating the same $+0\ nu$ female successively with a $+0\ nu$ male and a $+p^i\ nu$ male. Progeny carrying only the $p^i\ nu$ organizer lived for 3 days longer than the anucleolate progeny ($0/0\ nu$).

Usefulness of the $p\ nu$ Mutants of *Xenopus*

The $p\ nu$ variants described in this report, and called mutants on account of the Mendelian inheritance of the $p\ nu$ conditions through meiosis, have been shown to have the following characteristics: (1) they are characterized cytologically by the presence of nucleoli of unequal size in most cells; (2) they occur quite frequently in natural populations and the $p\ nu$ mutation probably arises during meiosis; (3) such mutants fall into two classes, defined according to the viability or inviability of individuals whose only nucleolar material is formed by one $p\ nu$ organizer ($p/0\ nu$ and $p^i/0\ nu$ mutants).

Partial nucleolar mutants of the kind described here will be of particular value for the genetic analysis of ribosomal RNA genes whenever the $p\ nu$ nucleolar organizers are found to have less than the normal number of these genes. An analysis of the ribosomal RNA synthesized by different $p\ nu$ mutants may make it possible to determine if the highly reiterated ribosomal RNA genes are heterogeneous. If they are, then complementation studies using different $p\ nu$ mutants would be invaluable in any attempt to investigate the nature of these differences. If ribosomal RNA genes consist of repeated identical sets, then $p\ nu$ mutants would make it possible to determine the minimum number of such sets necessary for normal cell growth and function. Results to be presented elsewhere show that the $p^i/0\ nu$ mutant described here synthesizes ribosomal RNA at a reduced rate¹⁷ and has considerably less than the haploid number of ribosomal RNA genes¹⁸.

Mutants involving partial deletions of ribosomal RNA genes have been collected in *Bufo marinus*⁷ and *Drosophila melanogaster*¹⁹. In spite of the great convenience of *Drosophila* for breeding experiments, we believe that $p\ nu$ mutants of *Xenopus* offer several important advantages for analysis of ribosomal RNA genes.

(1) The use of phase contrast microscopy to examine the nucleoli of a small number of cells taken from living embryos permits easy identification and collection of heterozygous $p\ nu$ mutants.

(2) *Xenopus* embryos are sufficiently large to permit the biochemical analysis of a single tadpole¹⁸. Unless this can be done, it is necessary to combine several individuals for a biochemical analysis. This could be a substantial disadvantage because siblings are not certain to have exactly the same genotype in view of the changes which can occur in the ribosomal RNA genes at meiosis.

(3) The maternal ribosome supply of *Xenopus* embryos makes it possible to study ribosomal RNA synthesis in lethal mutants having very small numbers of ribosomal RNA genes¹⁸.

(4) The use of *Xenopus* permits the vegetative propagation of mutant embryos by nuclear transplantation²⁰. The capacity of mutant cells for growth, as opposed to differentiation, can be tested by culturing cells from single tadpoles²¹.

Spotted Hyaena: Crusher, Gnawer, Digester and Collector of Bones

by

ANTONY J. SUTCLIFFE

Department of Palaeontology,
British Museum (Natural History),
Cromwell Road, London SW7

Studies in East Africa confirm that spotted hyaenas sometimes accumulate bones in their lairs. Four types of bone damage caused by the hyaenas are defined.

THE anthropologist, studying excavated bone remains, frequently faces the problem of distinguishing hominid-worked specimens (the earliest supposed examples being from deposits of Miocene age¹), from those damaged by other processes. Because the least robust parts of all bones are likely to be destroyed more readily than stronger parts, whatever the destructive process, bone fragments of similar appearance can result from different causes and special care must be taken to differentiate between them.

Brain, for example, has pointed out² that, in South Africa, desert weathering of bone fragments, followed by abrasion in sand disturbed by feet of animals and people, can lead to the formation of pseudo-tools; and that differential durability of goat bones, discarded by Hottentot tribesmen and gnawed by their dogs, can result in a disproportionate representation of the various skeletal parts³. Washburn has observed⁴ that eating by carnivores is normally a highly selective process; and, in Europe, palaeontologists have repeatedly remarked on the consistent form of bone remains supposed to have been left in caves by Pleistocene spotted hyaenas, compact bone surviving more readily than cancellous bone⁵⁻⁸. Dart, following his studies of australopithecine sites in South Africa, has questioned⁹ whether the European Pleistocene hyaena was in fact the traditionally accepted accumulator of bones, suggesting instead that the fractured hyaena remains found at such sites as Kirkdale Cave in Yorkshire should be attributed to early man. Thenius⁷ has commented on the close similarity between the fracturing of bones attributed by Dart to the osteodontokeratic culture of *Australopithecus prometheus* and that of bones fed by Zapfe¹⁰ to a spotted hyaena in the Schönbrunn Zoo, Vienna (see also Wolberg¹¹). Porcupines^{6,12,13}; leopards^{12,14}; tigers, lions, wolves and coyotes¹⁵; are further animals known to damage bones.

The nature of hyaena damage and the process of accumulation of hyaena damaged bones is especially complex and presents a constant potential source of

confusion for those studying remains from hominid sites. I propose to place on record here some observations on the habits of wild spotted hyaenas noted during field work in East Africa during 1960 and 1967.

Feeding and Bone Accumulating Habits of Spotted Hyaenas

The feeding and denning habits of spotted hyaenas have been previously studied by a number of workers. Hughes found¹⁶ that in South Africa, the spotted hyaena habitually feeds where it finds its food. He concluded that it carries away, if anything, only easily digested fragments suitable for feeding its young. Kruuk has shown¹⁷ that hyaenas are not only the proverbial scavengers but that, in the Ngorongoro Crater, Tanzania, they also chase and kill wildebeest and zebra. These are normally consumed in the open. Inspection, after about

Fig. 1. Details of carcass of a wildebeest, killed and partly eaten by spotted hyaenas in the Ngorongoro Crater, Tanzania. Photographed about 20 min after death. Note splintering of the tibia.

twenty minutes of a carcass of a wildebeest, killed there by spotted hyaenas under the observation of Kruuk and myself, showed that the ventral part of the rib cage had already been broken away, all the soft internal parts had been consumed, a tibia had been broken across and part was missing (Fig. 1).

Matthews, from his observations in East Africa¹⁸, recorded that spotted hyaenas always use a burrow or den of some sort as a nursery for their young. He described two types of lair: in natural cavities between granite boulders in small hills known locally as kopjes; and in burrows excavated in soft sediments. Hughes described¹⁹ similar lairs of both types in the Kruger National Park, South Africa, and also made an extensive search^{13, 16, 19, 20}, both in the field and through the press, for hyaena lairs which might be found to contain accumulations of bones. Nevertheless, the inspection of various lairs and the complete excavation of two of them did not reveal any accumulations of bones or of hyaena droppings. He concluded that the hyaena probably frequents caves, earths or rockshelters only when it has its young; that it does not habitually collect great quantities of bones in or near its lair; and that it does not foul the place where it sleeps or has its young.

During 1967, I inspected about twenty East African caves, the most important being on Mt Elgon (in Miocene agglomerate) and on Mt Suswa, Kenya (lava caves), with the object of looking for bone deposits. These caves differed from the hyaena lairs mentioned earlier in being large and easily explored throughout most of their distance. Although it was clear that many of these caves were frequented by hyaenas, especially in the daylight zone near the entrance, because splintered bone fragments and occasional droppings (including some groups of droppings in the dark zone) were present, nowhere could the bones be described as an accumulation. But investigation of a number of lairs of spotted hyaenas, similar to those described by Matthews and Hughes, produced strikingly different results.

In the Queen Elizabeth Park, Uganda, two burrows in alluvial sediment (both too constricted for human access) were, with permission from the Director of National Parks, completely excavated. The first was of

Fig. 2. Bone remains obtained by excavation from the entrance tunnels of a spotted hyaena lair in the Queen Elizabeth National Park, Uganda. They include skulls of kob, baby hippopotamus and warthog; antelope jaws and (centre) a humerus of a baby elephant.

Fig. 3. Interior of a spotted hyaena lair, near Kajiado, Kenya. Note human cranium and remains of domestic animals.

simple plan with a single terminal chamber, about three feet below ground level, opening to the surface by a trifurcating tunnel. A few fragments of bones of antelopes and of a juvenile hippopotamus were found in the access tunnel. The terminal chamber was empty except for the complete skeleton of a baby spotted hyaena and one dropping. The second lair was more complicated, having a central chamber (which was empty) and a series of tunnels leading to at least ten openings situated around it. The tunnels contained numerous bone remains, including skulls of baby hippopotamus, warthog and kob, bones of buffalo, a humerus of a baby elephant (Fig. 2) and a fragment of a skull of a baby hyaena. Many of these remains were splintered and gnawed.

A spotted hyaena lair near the side of the lake in the Ngorongoro Crater was found to be sufficiently large to permit human access for a short distance inside some of its entrances, although all tunnels soon became too small for further progress. A substantial quantity of bones, principally of zebra and wildebeest, but also including an almost complete skull of an adult hyaena, was collected with a pole from inside the lair. An extensive scatter of bone fragments, many splintered, was also found outside. There could be no doubt that hyaenas were the principal occupants of the lair and were responsible for most of the bones found there. I was rewarded with a view of the head and shoulders of a three-quarter grown hyaena inside a tunnel before the animal nervously backed away. Another partly grown hyaena was seen carrying a bone into another hole in the crater floor.

I also inspected two further hyaena lairs, near Kajiado, Kenya. Both were natural horizontal cracks in lava which apparently extended some distance into the rock, but were too low for human exploration beyond about 15 feet. Both tunnels contained substantial quantities of bones (including those of domestic donkey, cow and dog), one of them for a distance of at least 25 feet. In this lair were also ostrich bones, part of an ostrich egg, a human jaw, three human crania (Fig. 3) and a few other human remains. A great quantity of bone fragments were also strewn about outside. Both lairs could reliably be attributed to spotted hyaenas. Both were close to Masai villages, whence the remains of the domestic animals doubtless originated. Three local Masai villagers independently expressed the opinion that human skulls had been carried to the lair from Kajiado Hospital cemetery, about two and a half miles away, by hyaenas. An inspection of the cemetery showed that many of the graves had indeed been plundered by hyaenas and that there were innumerable splintered human bone fragments scattered around them.

Fig. 4. Gnaw marks caused by the milk teeth of spotted hyaenas on a humerus and metatarsal of wildebeest, from inside a lair in the Ngorongoro Crater (scale in cm) (photo by courtesy of BM(NH)).

From these observations it seems that although adult East African spotted hyaenas normally feed in the open, young animals nevertheless commonly carry bones into their lairs. These bones may have originated a considerable distance away. The bones found in the lairs are predominantly remains of animals killed or scavenged locally (principally herbivores), generally less than 5 per cent being of spotted hyaenas. Hyaena droppings are usually absent. Lairs containing young hyaenas are characteristically too small for human ingress and should therefore generally be distinguishable from hominid dwelling caves on grounds of size.

My present investigations suggest that there may be regional differences in the behaviour of spotted hyaenas, those in East Africa having a greater tendency to carry bones to their lairs than those of South Africa although the reason for this is probably merely the proximity of the food supply. The British Pleistocene hyaena (sometimes represented by deposits composed of 90 per cent hyaena remains, contained in tunnels too small to be suitable for human habitation) may perhaps have hibernated in caves, like the great cave bear, *Ursus spelaeus*. No comparable accumulations of hyaena bones, recent or fossil, have yet been recorded from any African site.

Types of Bone Damage caused by Spotted Hyaenas

From the above studies, four types of bone damage caused by spotted hyaenas may be defined:

Type 1: splintering of bones by adult animals. The adult spotted hyaena commonly splinters bones, with the aid of its powerful premolars. The structural specialization whereby it can seize and crush its prey has been described by Buckland-Wright²¹. A typical splintered bone is shown in Fig. 1. A study of bone fragments from the sites described above shows that there is a regular pattern of those parts of bones which survive and those which are eaten; the robust parts surviving, whereas cancellous bone is more commonly destroyed. This situation is especially well demonstrated by human remains collected around the graves at Kajiado Hospital cemetery. These consisted predominantly of the shafts of tibiae, femora and humeri, all with their ends missing, some skull remains and very little else. It is significant that the shafts of human limb

bones are composed of compact bone, the ends mostly of cancellous bone. Similar bone damage has been observed by Brain, who experimentally fed baboon remains to cheetahs¹². These animals ate the whole vertebral column, hands and feet, and also caused damage to the ends of the limb bones.

Similarly, the distal ends of artiodactyl humeri tend to survive, whereas the proximal ends are often missing; and bovid and equid metapodials often survive complete. The ascending ramus and ventral margins of herbivore jaws are frequently bitten away and the upper part of a human skull is more likely to survive than the facial region. Similar patterns of bone breakage can be found for all skeletal parts of all animals.

Type 2: gnawing of bones by juvenile animals. Juvenile hyaenas which still have their milk dentition apparently cannot splinter bones, as the adults do, but gnaw them, leaving striations at right angles to the elongation of bones (Fig. 4). Examples of such gnawing were found on many of the bones extracted from the lairs in the Queen Elizabeth Park and the Ngorongoro Crater, described earlier. Because most such bones had originally been torn from the carcass by adult hyaenas, before being brought to the lair, both type 1 and type 2 bone damage were frequently found on the same specimen. Close inspection of such gnawing shows the striations to have been formed by tearing and that they are seldom straight for more than a short distance. The striations are probably indistinguishable from the gnawings of other medium-sized carnivores (similar gnawing by coyotes has been illustrated by Miller¹⁵), but they are quite distinct from the chiselled tooth marks of porcupines and from marks made by knives. Continued gnawing by juvenile hyaenas can sometimes lead to the formation of holes in bones. In this way a captive juvenile spotted hyaena, owned by M. Croydon, of Nairobi, created a "window" in the shaft of an antelope metatarsal, close to its distal end.

Type 3: scooping out of cancellous bone. Zapfe, from his studies at the Schönbrunn Zoo, observed¹⁰ that the scooping out of spongy bone is characteristic of carnivore feeding. This seems to be a feature predominantly of bones too large for hyaenas to break across. It is well shown in a bovid femur gnawed by Croydon's captive juvenile hyaena, where the walls of the greater trochanter were left standing as a thin circle of bone around a scooped out central pit.

Type 4: damage by partial digestion. In the course of feeding, adult hyaenas frequently swallow substantial fragments of bones. After feeding they subsequently regurgitate everything indigestible. Numerous piles of regurgitated food material were found around the

Fig. 5. Bones of juvenile wildebeest from the Ngorongoro Crater, partly digested and subsequently regurgitated (in the open) by spotted hyaenas. Note circular holes and bone fragment lodged inside the uppermost specimen (scale in mm) (photo by courtesy of BM(NH)).

entrances of the lair in the Ngorongoro Crater, described earlier. These consisted not only of partially digested bone fragments and teeth, mostly of juvenile wildebeest (Fig. 5) but also hoofs and great quantities of hair, some of it compacted tightly inside the bone fragments. Distinctive features are: scalloping of the bone surface; knife sharp edges between two eroded faces; and even circular holes. The remains have the appearance of the hyaena's gastric juices having been circulated around them under pressure, since not only were the bones packed with masses of hair, but some of the hairs were threaded through the minute channels in the bone and small pieces of bone were even wedged inside the larger fragments. Although these regurgitated tooth and bone remains, especially bone fragments with circular holes in them, could be mistaken for human artefacts (Kitching, for example, has pointed out²² that the object from Pin Hole Cave, Derbyshire, previously thought to be a "bull-roarer" did, in fact, result from erosion by gastric juices, probably of a hyaena) they are generally distinctive and should be easily recognized by those studying damaged bone remains.

I thank the Director of National Parks of Uganda, who gave permission to excavate hyaena lairs; J. Cooke, A. Perkins and J. Simons who showed me the caves; and

M. Croydon, H. Kruuk, C. Spinage and C. Buckland-Wright, who showed me hyaena lairs and generously shared their own observations.

Mass Fractionation and Isotope Anomalies in Neon and Xenon

by
P. K. KURODA
O. K. MANUEL

Department of Chemistry,
University of Arkansas,
Fayetteville, Arkansas 72701

The neon and xenon isotope anomalies observed in meteorites can be interpreted in terms of a mass fractionation, which is common for both elements. It is not necessary to assume the existence of large excesses of fission-type xenon in carbonaceous and gas-rich chondrites.

THE role of mass fractionation in neon and xenon isotope anomalies has never been clearly understood. Reynolds¹ discussed this problem and reported it as "unexplained isotope anomalies in neon and xenon". Marti² has recently suggested that terrestrial atmospheric and solar-type xenon may be related to each other by a strong mass fractionation process, while trapped chondritic xenon might be related to solar-type xenon by superimposing fission-xenon components with the required relative mass yields on the latter. According to Anders and Heymann³, the fission component found in carbonaceous and gas-rich chondrites was not derived from an actinide element ($Z = 89$ to 103), or from a transition metal between $Z = 104$ and 111, but from a more volatile progenitor ($Z = 112$ to 119).

The isotopic compositions of neon in various chondrites seem to be quite complex. According to Pepin⁴, a number of different components of neon occur in nature, and there is no sign that diffusive fractionation is responsible for any of the isotopic variations. Manuel⁵, on the other hand, reported that the isotopic composition of neon observed in the gas-rich chondrite Fayetteville could be produced from a mixture of primordial neon, cosmogenic neon and highly mass-fractionated primordial neon.

We re-examine here the published xenon isotope ratio data from the stepwise heating experiments on the Fayetteville⁶, Renazzo⁶, Mokoia and Chainpur⁷ chondrites. These experimental data are plotted in Fig. 1 together

with the xenon isotope ratios in the atmosphere⁸, in average carbonaceous chondrites⁹, and in the 800° fraction of lunar fines¹⁰.

The solid lines I, II, III and IV in Fig. 1 correspond to the equations

$$y = 5.15x - 3.03 \quad (1)$$

$$y = 5.07x - 3.58 \quad (2)$$

$$y = 1.17x - 0.92 \quad (3)$$

$$y = 0.735x - 0.649 \quad (4)$$

where $x = (^{134}\text{Xe}/^{136}\text{Xe})_{\text{met}}$, $y = (i\text{Xe}/^{136}\text{Xe})_{\text{met}}$ and $i = 132, 131, 130$ and 128.

Equations (1)–(4) can be derived from a general equation

$$f = \left(\frac{(i\text{Xe}/^{136}\text{Xe})_{\text{met}}}{(i\text{Xe}/^{136}\text{Xe})_{\text{atm}}} - 1 \right) \cdot \frac{136}{(136 - i)} \quad (5)$$

where f may be defined as a mass fractionation factor for the xenon isotopes.

The dashed lines a , b , c and d in Fig. 1 are parallel to the straight lines I, II, III and IV, respectively, and pass through most of the experimental points. By extrapolating the straight lines a , b and c to the left, we can find the values of $^{134}\text{Xe}/^{136}\text{Xe}$, $^{132}\text{Xe}/^{136}\text{Xe}$ and $^{131}\text{Xe}/^{136}\text{Xe}$, when the $^{130}\text{Xe}/^{136}\text{Xe}$ ratio become zero. From these values,

Fig. 1. A comparison of atmospheric⁶, lunar¹² and AVCC⁹ xenon with the xenon released from the Fayetteville⁵, Renazzo⁸, Mokoia and Chainpur⁷ chondrites. The solid lines through atmospheric xenon show the isotopic composition of mass fractionated xenon, the dashed lines show the isotopic composition of mass fractionated AVCC xenon, and the dotted lines show the isotopic composition of xenon produced by mixing AVCC xenon with the "fission" xenon defined by Pepin⁴. The xenon coordinates are labelled on the lower abscissa and on the left ordinate. The isotopic composition of atmospheric¹³ and lunar¹² neon is also compared with the neon released from Fayetteville⁵ and Renazzo⁸. The neon coordinates are defined on the upper abscissa and on the right ordinate.

we can secure the $^{131}\text{Xe} : ^{132}\text{Xe} : ^{134}\text{Xe} : ^{136}\text{Xe}$ ratio, which represent the mass-yield distribution of the "unknown" fission component discovered by previous investigators.

According to Pepin⁴, this ratio is

$$^{131}\text{Xe} = 0.25 \pm 0.13, \quad ^{132}\text{Xe} = 0.48 \pm 0.08, \quad ^{134}\text{Xe} = 1.000 \quad \text{and} \\ ^{136}\text{Xe} = 1.43 \pm 0.06$$

The dotted lines in Fig. 1 connect AVCC xenon⁹ to the above mass-yield distribution. The dotted "fission" lines are distinct from the dashed "mass fractionation" lines primarily in the regions to the left of the experimental data points, except for the $^{132}\text{Xe}/^{136}\text{Xe}$ ratios, where several of the data points lie below both lines. This behaviour is to be expected if these chondrites contain xenon isotopes from the spontaneous fission of 82 m.y. ^{244}Pu . The amounts of fissionogenic xenon indicated by the deviations of the $^{132}\text{Xe}/^{136}\text{Xe}$ ratios below the mass fractionation line are in all cases less than the amounts of xenon produced by ^{244}Pu in Pasamonte¹¹.

Are the xenon isotope ratio data caused either by mass fractionation or by fission of an unknown element? Fission of an unknown element is certainly an attractive explanation, because the unknown element may be one of the superheavy elements ($Z=112$ to 119), as suggested by Anders and Heymann³. But, the fact that the mass-yield distribution deduced from the xenon isotope data is so close to that deduced from the mass fractionation

theory is most disquieting. Moreover, this explanation does not help us to understand the neon isotope anomalies, which are just as spectacular as the xenon isotope anomalies. Mass fractionation, on the other hand, is a promising explanation, because it helps in understanding the phenomena of isotope anomalies in rare gases in general.

Fig. 1 compares the neon data obtained by Manuel⁵ and by Reynolds and Turner⁶ with lunar¹² and atmospheric¹³ neon. The neon isotope ratios for meteorites have been corrected for cosmogenic neon by the method described by Manuel⁵, but no corrections were made on the lunar and atmospheric neon ratios. The experimental data fit line V in Fig. 1 which is defined by

$$y = 1.481 \times 10^{-3}x + 0.01452 \quad (6)$$

where $x = (^{20}\text{Ne}/^{22}\text{Ne})_{\text{met}}$ and $y = (^{21}\text{Ne}/^{22}\text{Ne})_{\text{met}}$.

By writing the equation (5) in a more general form

$$f = \left\{ \frac{(X^i/X^j)_{\text{met}}}{(X^i/X^j)_{\text{atm}}} - 1 \right\} \cdot \frac{j}{(j-i)} \quad (7)$$

where X may be any one of the rare gas elements and i and j are the mass numbers, we can derive equation (6) from equation (7) and also calculate the values of f for the neon isotopes. The f values for neon and xenon are also indicated on the abscissae of Fig. 1. Similar relationships between $^{20}\text{Ne}/^{22}\text{Ne}$ and $^{36}\text{Ar}/^{38}\text{Ar}$ and also between $^{20}\text{Ne}/^{22}\text{Ne}$ and $^{20}\text{Ne}/^{36}\text{Ar}$ in some chondrites were found several years ago by Signer and Suess¹⁵. Kuroda¹⁶ attempted unsuccessfully to calculate the effect of mass-fractionation on atmospheric xenon using the equation given by Suess¹⁷

$$-\log \frac{N_{\text{ter}}}{N_{\text{sol}}} = 10 \cdot 0.045 M/m_1 + 7.1 \quad (8)$$

where N_{ter} and N_{sol} are the terrestrial and the cosmic abundances of the rare gases with the mass M/m_1 , respec-

Fig. 2. A comparison of the abundance pattern of noble gases predicted by equation (9) with the abundances of noble gases in the atmosphere, the Murray carbonaceous chondrite, and sixteen other meteorites containing primordial noble gases. The data points are from Signer and Suess¹⁵.

tively. Equation (8) gives $f = +0.325$ for cosmic xenon and $f = 13.62$ for cosmic neon, calculated for the $^{134}\text{Xe}/^{136}\text{Xe}$ and $^{20}\text{Ne}/^{22}\text{Ne}$ ratios, respectively. Obviously, the Suess equation does not predict the magnitudes of the effect of mass fractionation that are observed in atmospheric noble gases.

In deriving equation (8), Suess assumed that essentially all of the Earth's noble gases reside in the atmosphere where there is no evidence of any significant depletion of Kr from Xe, although both gases are depleted to about 10^{-7} of their cosmic abundances. The term 7.1 in equation (8) represents the loss of gases by a non-fractionating process to $10^{-7.1}$ of their cosmic abundance. In chondrites, however, the abundance pattern of noble gases shows a separation of krypton from xenon by about a factor of 10, and recent work on terrestrial samples¹⁸ indicates that fractionation patterns for noble gases in chondrites and in the Earth are very similar if the preferential retention of xenon in certain terrestrial rocks and minerals is taken into account.

Because the degree of mass fractionation observed in meteoritic noble gases varies with the extraction temperature, it is apparent that the isotope fractionation of a gas observed in different temperature fractions may not be related to the extent to which the total abundance of the gas is depleted below its cosmic abundance. Nevertheless, the approximately equal range of f values for neon and xenon shown in Fig. 1 can be obtained by removing the term 7.1 from the Suess equation and adjusting the coeffi-

Fig. 3. Temperature release experiments on the gas-rich chondrites Fayetteville and Pesyanoe. Experimental data (---) were obtained by Manuel⁸ and Marti⁹, respectively. The calculated curve for Fayetteville (—) was obtained from the neon data by Manuel, assuming that the mass fractionation process is common for neon and xenon. Small contributions from the neutron capture and cosmic-ray spallation reactions at mass number 132 are disregarded in the calculations.

Fig. 4. Temperature release experiments on the carbonaceous chondrites Murray and Renazzo. Experimental data (---) were reported by Reynolds¹⁴ and Reynolds and Turner⁶, respectively. The calculated curve for Murray (—) was obtained from the neon data reported by Pepin⁴. The neon data for Renazzo were reported by Reynolds and Turner⁶. Because of the presence of cosmic ray-produced neon, the neon data are unreliable above $1,000^{\circ}\text{C}$. Small contributions from the neutron capture and cosmic-ray spallation reactions at mass number 132 are again disregarded in the calculations.

cient to fit the abundances of primordial noble gases

$$-\log D = (10 \pm 1)e^{-0.005m} \quad (9)$$

where D is the ratio of the terrestrial or meteoritic to the cosmic abundances of a rare gas isotope with mass number m . Fig 2 compares the fractionation pattern of noble gases predicted by equation (9) with the abundances of primordial noble gases in the atmosphere and the Murray chondrite. The range of noble gas abundances for sixteen other meteorites is also shown.

Equation (9) predicts $f = +7.6$ for cosmic xenon and $f = +2.5$ for cosmic neon, whereas the Suess equation predicted much smaller f values for xenon (0.325) than neon (13.62). From Fig. 1, it seems that approximately equivalent f values will relate atmospheric neon and xenon to solar-type neon ($f = +3.24$) and xenon ($f = +3.58$), and that there is an approximately equal range of f values observed in the temperature release patterns for neon and xenon from meteorites. To test for a common fractionation of neon and xenon isotopes in the temperature release patterns from carbonaceous and gas-rich meteorites, we calculate f values from the neon data and use these values to calculate the δ_{132}^{136} values for xenon, defined as

$$\delta_{132}^{136} = 100 \left\{ \frac{(^{136}\text{Xe}/^{132}\text{Xe})_{\text{met}}}{(^{136}\text{Xe}/^{132}\text{Xe})_{\text{atm}}} - 1 \right\} \quad (10)$$

Figs. 3 and 4 compare the calculated and experimental values from the stepwise heating experiments on a number of meteorites.

Although the agreement is not perfect, the theory does predict the general behaviour of the xenon temperature release patterns. In the case of Fayetteville, there is a minimum at 1,000° C. The release pattern for Pesyanoe seems to be similar to that for Fayetteville. A peak is observed just below 1,000° C in the cases of Murray and Renazzo. A sharp minimum observed at Renazzo 600° C fraction corresponds to a minimum in the calculated curve (—) at 300°–400° C fractions.

The crucial test of the proposed new interpretation for the rare gas isotope anomalies in terms of mass fractionation should come from the studies on the isotope anomalies in krypton. The krypton data are scarce and we are now in the process of securing reliable krypton data in our laboratories.

This investigation was supported by the US National Science Foundation.

Radio Pulses from Extensive Air Showers

by

H. R. ALLAN

R. W. CLAY

Imperial College, London

J. K. JONES

University of Leeds

A relationship has been obtained between radio pulse amplitudes and the shower parameters given by particle detectors.

RADIO pulses associated with extensive air showers have been detected by many investigators during the past five years (for references, see ref. 1). Quantitative information is still sparse, however. An average lateral distribution function for the radiation at 30 MHz has been given by Vernov *et al.*² but only a small number of showers were available, and fluctuations between one shower and another were very large. Similar trouble with fluctuations has been experienced at Haverah Park³, and by the Ann Arbor group at Chacaltaya⁴. For this reason, most results have been expressed statistically, by the proportion of showers in different categories that give detectable radio pulses (see, for instance, ref. 4). At Haverah Park we have now succeeded in obtaining what is essentially a 1:1 relationship between radio pulses amplitude and the shower parameters given by the particle detectors. Some scatter remains (~a factor of two in radio pulse amplitude) but this can reasonably be attributed to the known uncertainties in the particle parameters.

The improvement has come about chiefly by the adoption of 55 MHz as the principal measuring frequency. For the showers detected at Haverah Park, with primary energies $E_p \sim 10^{17}$ to 10^{18} eV, the radio pulses are only a few times larger than the r.m.s. background noise. Most of the noise power is in a quasi-thermal component, but at the frequencies we have used previously (32 MHz and 44 MHz) there is a second component in the background, consisting of bandwidth-limited pulses typically five times larger than the thermal component and occurring at intervals of a few μ s. When such a pulse occurs in time coincidence with the arrival of an air shower, there is no way of distinguishing it from a genuine radio pulse originating in the air shower. The large background pulses are numerous at 32 MHz, less frequent at 44 MHz and at

55 MHz they are not observed at all. From the way their number varies between summer and winter⁵ we speculate that they may be dependent on seasonal changes in the ionosphere, analogous perhaps to the anomalous effects at lower frequencies discussed by Appleton and Piggott⁶ and by Minnis⁷. At 32 MHz, measurements on air shower radio pulses are practicable only during the winter, and even then some 20 per cent of the pulses ascribed to the air showers are probably spurious¹. At 55 MHz we are able to identify an air shower pulse unequivocally if it has an amplitude appreciably larger than the thermal background.

All measurements on the radio pulses have been made during the night (0–0800 h) because of the additional man-made interference experienced during the day from sound and television broadcasting.

In our present measurements we used a radio receiving system very similar to that described in ref. 1. We have six radio receivers, two each at 32 MHz, 44 MHz and 55 MHz, with corresponding bandwidths 3 MHz, 4 MHz and 2 MHz. The antennas are located at a single site 80 m from the centre of the Haverah Park 500 m array. They are oriented to pick up the two horizontal components of the radiation (geomagnetic N–S and E–W) at each frequency. The polar diagram of reception sensitivity in each case consists of a single lobe with its maximum towards the zenith and a null towards the horizon. The receiver outputs are passed through delay cables and linear detectors to separate oscilloscope displays. When the particle array detects a shower the receiver outputs are photographed on a timebase of duration 5 μ s. A time-marker allows one to locate the point on each time base corresponding to the time of arrival of the shower particles.

Over a period of six months, a total of forty-nine radio

showers were identified by the pulses they produced in the 55 MHz receivers. A pulse was accepted as genuine if it occurred at the expected arrival time and was more than twice the amplitude of any other pulse on the trace. We believe all these assignments to be correct; indeed, the results of analysis when rather smaller pulses are also accepted differ only marginally from the ones we shall describe. At 32 MHz and 44 MHz there were only sixteen showers with pulses twice as large as any background pulse at the expected arrival time. Smaller pulses occurring at the expected time were accepted for analysis as well, provided the same shower had produced an unambiguous pulse at 55 MHz. In this way, additional data were obtained from twenty-four showers at the lower frequencies, but we recognize that some of the pulses may be spurious. Accordingly we give less weight to the 32 MHz and 44 MHz data, and concentrate on the 55 MHz results.

The receiver gains were measured with the aid of a pulse-modulated r.f. signal generator and an impulse generator which provided a pulse ~ 10 ns long and of variable amplitude. The observed pulse heights were thereby converted to equivalent voltages at the receiver input terminals. From the calculated antenna gain in the direction of the incoming radio pulse (that is, the direction of the shower axis), and the measured system bandwidth, the voltages were then converted to field strengths per unit bandwidth in the horizontal plane along the geomagnetic N-S and E-W directions. Given these two components of the field and the knowledge that the total electric field vector \mathcal{E} lies in a plane perpendicular to the shower axis, we could thus determine its direction, in other words, the polarization, and also the amplitude of the frequency component \mathcal{E}_ν measured in $\text{V m}^{-1} \text{MHz}^{-1}$ at the frequency ν .

Our chief interest is to relate \mathcal{E}_ν to the relevant parameters of the air shower as measured by the particle array. We expect \mathcal{E}_ν to depend on (a) the primary energy E_p ; (b) the perpendicular distance R from the antenna to the shower axis; (c) the direction of the shower axis. To specify the direction of the shower axis requires two angles. For these we choose θ , the zenith angle, and α , the angle between the shower axis and the geomagnetic field lines. The choice of α , rather than the more familiar azimuthal angle ϕ is made to simplify the analysis, for much evidence already exists to indicate that geomagnetic charge separation is the dominant mechanism of radio emission¹.

With the limited data available, it is not possible to map completely the four-fold dependence of \mathcal{E}_ν on the variables E_p , R , θ and α . Instead, we build up a trial function based partly on the data and partly on theoretical ideas about the dependence of \mathcal{E}_ν on the separate variables; we then look to see how closely the formula as a whole is consistent with all the experimental data.

For all showers, and at all three frequencies (where measurement was possible) the polarization was found to be compatible with that predicted by geomagnetic charge separation. We compared the measured and the predicted ratios of the pulse amplitudes in the horizontal N-S and E-W directions. Only in two cases, with pulses at 32 MHz and 44 MHz that had passed the less onerous acceptance criteria, and were smaller than other background pulses on the trace, was there a numerical discrepancy greater than the error of measurement. We presume that these pulses were in fact spurious.

We tested the other possible radiation mechanisms listed in ref. 1 by the same method, but the correlations so obtained between predictions and measurements were not good. Tentatively, therefore, we assume that the radiation is due wholly to geomagnetic charge separation (in line with at least one theoretical analysis^{9,10}) and accept the implication that \mathcal{E}_ν is proportional to the sine of the angle made by the shower axis with the Earth's field: $\mathcal{E}_\nu \propto \sin \alpha$.

We now consider the dependence of \mathcal{E}_ν on the primary energy E_p . The theory of coherent radiation in its simplest form would require $\mathcal{E}_\nu \propto E_p$, but this may be modified by two secondary effects. As E_p increases, the shower maximum comes closer to the antenna, and on this basis \mathcal{E}_ν could increase more rapidly than E_p . On the other hand, path differences between different parts of the shower and the antenna become progressively greater; this leads to a loss of coherence and to a slower increase of \mathcal{E}_ν with E_p . In an earlier publication¹ we suggested that loss of coherence was the more important effect and that (for E_p between 10^{17} and 10^{18} eV) $\mathcal{E}_\nu \sim E_p^{1/2}$. We now recognize that this earlier analysis was at fault, and that the $E_p^{1/2}$ relation arose from the effect of background noise on the measurements. This reduces the apparent dependence, because for the smaller values of E_p a larger proportion of noise pulses is included among those accepted as genuine. Let us suppose that the dependence of \mathcal{E}_ν on E_p can be expressed by assigning an appropriate value to the exponent β in the equation $\mathcal{E}_\nu \propto E_p^\beta$. We now define a quantity $P = [\mathcal{E}_\nu/E_p^\beta \sin \alpha]$ and call it the normalized pulse amplitude. P will be a function only of R and θ , so if we take showers in a limited range of zenith angles and plot P against R , the points should define a lateral distribution function for the radiation. Implicit in this procedure is the assumption that β is independent of R , in other words, that the lateral distribution has the same shape for different values of E_p . The correctness of this assumption, and of the value of β adopted, can be assessed by the extent to which the experimental points cluster about a unique line for $P = P(R)$.

Our experimental data lead us to adopt a value of the exponent $\beta = 1$. The evidence for this is particularly convincing at $\nu = 55$ MHz and $\theta < 35^\circ$, that is, at the frequency least affected by radio interference and in the zenith angle range where shower analysis from the particle array is at its most reliable. Fig. 1 shows the experimental normalized pulse amplitudes for $\nu = 55$ MHz plotted against R . For showers with $\theta < 35^\circ$ (Fig. 1a) the scatter of the experimental points about the mean line is small. If, for instance, we choose to attribute this scatter entirely to errors in R , then the implied r.m.s. error would be ~ 28 m; such a value is considered to be typical of the actual errors in shower axis location at Haverah Park⁸. The assumption that $\beta = 1$ is therefore compatible with the data.

The showers represented in Fig. 1a have energies E_p between 10^{17} and 10^{18} eV. The only exception is the isolated point at $R = 600$ m which relates to a rare shower with $E_p \sim 1.5 \times 10^{19}$ eV. The points due to the larger showers ($E_p > 3 \times 10^{17}$ eV) are distributed evenly among the other points, and there is no hint of any systematic shift with energy. If, on the other hand, we test the hypothesis $\beta = 0.5$ and plot the quantity $[\mathcal{E}_\nu/E_p^{0.5} \sin \alpha]$ against R , then first, is there an increased scatter about the median line; second, the higher energy showers give points which all fall on the high side of that line. We infer that for E_p between 10^{17} and 10^{18} eV the true value of β is certainly greater than 0.5: we guess it cannot be less than 0.8. The evidence is thus in favour of the value $\beta = 1$ for showers with energies between 10^{17} and 10^{18} eV. Unfortunately, little can be said about β at higher energies, despite the presence of a point in Fig. 1a for $E_p = 1.5 \times 10^{19}$ eV at $R = 600$ m. This point stands well apart from the others, none of which has $R > 250$ m. In Fig. 1a it is normalized just like the others, assuming $\beta = 1$. But a change in the assumed E_p dependence at 1.5×10^{19} eV would merely result in a change in shape of the lateral distribution function beyond 250 m; it leads to no inconsistencies with the data.

Fig. 1b, with data for $\nu = 55$ MHz, $35^\circ < \theta < 50^\circ$, and shower energies $10^{17} - 3 \times 10^{18}$ eV provides supporting evidence in favour of $\beta = 1$, though the scatter is worse than in Fig. 1a. This scatter may be attributed partly to the uncertainties in estimating E_p at large zenith angles, and

partly to changes in the lateral distribution function itself over the rather large range of θ included in the one diagram.

The lateral distribution function for $\nu = 55$ MHz was discussed above in relation to the E_p dependence. We find that for each frequency and zenith angle interval a convenient representation of the distribution is the function $P \propto \exp(-R/R_0)$ where R_0 gives a measure of the lateral spread of the radiation and has different values for different ν and θ . The continuous lines in Fig. 1 are based on the formula with R_0 chosen to give the best fit. For $\nu = 55$ MHz and $\theta < 35^\circ$, $R_0 = (100 \pm 10)$ m. R_0 increases with increasing zenith angle and with decreasing frequency; at 55 MHz and $35^\circ < \theta < 50^\circ$, $R_0 \approx 170$ m, while at 32 MHz and $\theta < 35^\circ$, $R_0 \approx 140$ m. The change is in the direction to be expected from simple geometrical and diffraction considerations, but the measurements are too rough to establish any quantitative relation.

The value of R_0 found for $\nu = 32$ MHz is quite compatible with the data on lateral distribution found by the Moscow group². Their results are expressed as power-law exponents for the dependence of \mathcal{E}_ν^2 on R ; $\mathcal{E}_\nu^2 \propto R^{-n}$, where n varies with R . The measurements of \mathcal{E}_ν^2 are made for different values of R in the same shower, so the Moscow results do not depend, as do ours, on the assumption that the lateral distribution is independent of E_p .

Our measurements show that changes in zenith angle θ have two effects on the radio pulse amplitudes. First (as already discussed) the parameter R_0 in the lateral distribution function increases with θ . Second, there is a general falling off in pulse amplitude by a factor ~ 2 as θ increases from 0° to 50° . As a convenient way of expressing this trend we write $\mathcal{E}_\nu \propto \cos \theta$. Both effects may be interpreted as effects of geometry, related to the increasing distance of shower maximum from the antenna as θ increases.

Because R_0 is frequency dependent, there is no unique dependence of \mathcal{E}_ν on ν ; one must specify the distance from the shower axis, R , at which the spectrum is required. Theoretical calculations^{9,10} suggest that different frequency components of the radiation are associated with shower particles of different kinetic energies E , the higher frequencies depending on the higher energy particles. At high energies (> 100 MeV) scattering is small and the approximation A of cascade theory is valid. For pulses observed on the shower axis the motion of these high energy particles is expected to give a spectrum with \mathcal{E}_ν independent of ν over a wide frequency range. Our present measurements are not precise enough to establish this prediction as a fact, but they are consistent with it. Our measurements at 2 MHz, published previously¹¹, give a considerably larger value of \mathcal{E}_ν at the lower frequency; this too is in line with the theoretical prediction.

The discussion and conclusions reached above can be summarized in a single equation

$$\mathcal{E}_\nu = 25 \left[\frac{E_p}{10^{17}} \right] \sin \alpha \cdot \cos \theta \cdot \exp \left(\frac{-R}{R_0(\nu, \theta)} \right)$$

$\mu\text{V m}^{-1} \text{MHz}^{-1}$

for the ranges E_p , 10^{17} – 10^{18} eV, ν , 32–55 MHz and R , 0–300 m. The parameter R_0 has the value (100 ± 10) m for $\nu = 55$ MHz and $\theta < 35^\circ$. R_0 increases by a factor ~ 2 as θ increases from 0° to 50° and as ν decreases from 55 MHz to 32 MHz. Extrapolation beyond any of these

limits is hazardous; in particular we expect that \mathcal{E}_ν may increase less rapidly with E_p as E_p increases beyond 10^{18} eV.

Finally, we wish to emphasize that the scatter shown in Fig. 1 is representative of all showers recorded by the Haverah Park array, and not of a small sub-set of "radio showers". We re-examined the particle and radio records of some 200 showers which had not given a detectable radio pulse. In every case the expected pulse amplitude as predicted from the particle data by the equation above was below the acceptance threshold. The most common reason for this was that with $E_p \sim$ a few times 10^{17} eV the distance R was in excess of 300 m. Thus Fig. 1 indi-

Fig. 1. Normalized radio pulse amplitude, P , at 55 MHz as a function of distance R from the shower axis. The normalization is carried out assuming the amplitude is proportional to the total shower energy E_p and to the sine of the angle made by the shower axis with the Earth's magnetic field. The ordinate gives the field strength in $\mu\text{V m}^{-1} \text{MHz}^{-1}$ for a shower of total energy 10^{17} eV moving perpendicular to the Earth's field. a, Zenith angle $\theta < 35^\circ$; ●, shower energy $10^{17} < E_p < 3 \times 10^{17}$ eV; x, shower energy $3 \times 10^{17} < E_p < 10^{18}$ eV; +, $E_p = 1.5 \times 10^{19}$ eV. b, Zenith angle $35^\circ < \theta < 50^\circ$; x, showers with $35^\circ < \theta < 42^\circ$; ●, showers with $42^\circ < \theta < 50^\circ$.

cates, to within the accuracy of measurement, a unique functional relationship between radio pulse amplitude and the shower particle parameters.

We thank Messrs D. Pearce, J. Prah, D. Andrews and all our colleagues at Haverah Park for their helpful cooperation throughout this work.

Search for Millimetre-wave Emission from Blue Stellar Objects

ACCORDING to the list of Burbidge and Burbidge¹, there are now 30 "radio-quiet" quasi-stellar objects, or QSOs (hereinafter called blue stellar objects, or BSOs) with measured redshifts. The term "radio-quiet" here means that they were selected optically and have not been identified in any general survey of radio sources. A number of BSOs have been examined by several different observers for possible radio emission on wavelengths from 94 to 2 cm, nearly always with negative results. In spite of this lack of success, a new survey of BSOs at millimetre wavelengths was felt worthwhile. No extensive surveys have been made at less than 11 cm wavelength; Kellermann and Pauliny-Toth² observed only three BSOs at 2 cm, with no detections. Many known QSOs have high surface brightness and hence positive spectral indices at short centimetre wavelengths³; thus BSOs might well be detectable only at short wavelengths.

The present observations at 9.5 and 3.5 mm (31.5 and 85.3 GHz) were made in December 1969 and January 1970 with the National Radio Astronomy Observatory 36 foot dish at Kitt Peak, Arizona. The receiver r.m.s. output fluctuations for 30 s of ideal integration time were equal to 2.8 flux units (f.u.) at 3.5 mm wavelength, and 1.9 f.u. at 9.5 mm (1 f.u. = 10^{-26} W/m² Hz). Dicke-switched dual feed systems were used, producing two antenna beams separated by about three half-power beamwidths. Observations consisted of 30 s integrations, with the source alternating in the two beam positions. The integrations were continued until the r.m.s. noise level at each source position was less than 0.3 f.u. The data were taken over a wide range of hour angle, while the antenna polarization was fixed horizontally; thus the data are averages over a range of position angles. Flux density calibrations were made by observing the standard sources Saturn, Jupiter and DR 21.

The sources observed are listed in Table 1. In no case was a deflexion more than three times the 0.3 f.u. r.m.s. level observed, so that an upper limit of 1.0 flux units at both 9.5 and 3.5 mm wavelength can be placed on all sources. The wavelengths and flux levels reached by previous observers are also included in Table 1. The only definite detection is PHL 1222 by Braccisi⁴ at 11 cm. Lang and Terzian¹⁰ reported detection of seventeen BSOs at the 0.3 or 0.4 f.u. level, but their identifications have been questioned by Grueff⁸, who used a smaller antenna beam and found that most of the radio and optical positions he observed did not agree within the estimated errors.

Most of the BSOs in Table 1 have now been surveyed at a number of wavelengths from 94 cm to 3.5 mm, with no detectable emission. A possibility which the earlier observations did not exclude was that BSOs are compact

and have a high radio surface brightness, hence remaining synchrotron self-absorbed to very short wavelengths. QSOs with compact components of this type are known to exist—for example, 3C345, with a peak flux density of 20 f.u. at 8.5 mm, and 3C273, with a peak flux of 30 f.u. at 10 mm (ref. 3). The present observations show that any such components for BSOs must either be less than 1.0 f.u. peak or have a cut-off wavelength $\lesssim 3.5$ mm, which implies a radio surface brightness about ten times that of any QSO. Achieving such a high surface brightness with a brightness temperature less than 10^{12} K (the maximum allowed for a reasonable lifetime with inverse Compton scattering) would require a magnetic field $\geq 10^{-2}$ G, compared with estimates of $\sim 10^{-4}$ G for known QSOs³.

* Detected by B; 0.1 f.u. at 11 cm.

† LT report 1.2 f.u., but BLS report ≤ 0.5 f.u.

Sources listed in order of right ascension. The upper limit to the current observations is 1.0 flux unit at both wavelengths. Other observers, wavelengths, and upper limits are:

B, Braccisi⁴ (11 cm, 0.075 f.u.).

BLS, Braccisi, Lynds, and Sandage⁵ (75 cm, 0.5 f.u.; 11 cm, 0.2 f.u.).

BFGV, Braccisi *et al.*⁶ (75 cm, 0.75 f.u.).

FGF, Fanti-Giovannini and Fanti⁷ (75 cm, 0.25 f.u.).

G, Grueff⁸ (75 cm, 0.2 f.u.).

GR, Grewing and Ristow⁹ (11 cm, 0.4 f.u.).

KPT, Kellermann and Pauliny-Toth² (6 cm, 0.10 f.u.; 2 cm, 0.2 f.u.).

LT, Lang and Terzian¹⁰ (94 cm, 0.3 f.u.).

SW, Shapiro and Weinreb¹¹ (3.75 cm, 0.5 f.u.; 2 cm, 2.0 f.u.).

The upper limits quoted are three times the r.m.s. noise if limits are not stated specifically in the original paper.

A comparison of the optical properties of QSOs and BSOs shows no clear systematic difference that might explain the lack of radio emission. The list of Burbidge and Burbidge¹ shows few BSOs with $m_r \leq 16.8$, but above this limit the ratio of BSOs and QSOs in any given visual magnitude range is roughly constant. In any case, Longair and Scheuer¹² found no correlation between optical and radio magnitudes of 75 QSOs. They concluded that there was probably a wide dispersion in both radio and optical luminosities of QSOs. Concerning redshifts, 50 per cent of the BSOs have $z \leq 0.5$, compared with 24 per cent of the QSOs; but Bolton¹³ has recently found a lack of correlation between redshift and flux density at 2,700 MHz for QSOs, even for flat spectrum sources (spectral index ≤ -0.7).

It appears likely that BSOs are similar to QSOs but have sufficiently low radio emission to have escaped detection. This conclusion is not unexpected considering the relative luminosities of QSOs and galaxies. Heeschen¹⁴ has shown that QSOs and galaxies (particularly radio galaxies) form a continuous sequence on a plot of absolute radio luminosity against surface brightness. The observed range of QSO luminosities, however, is only 10^{43} to 10^{45} erg/s, compared with 10^{37} to 10^{39} erg/s for spiral galaxies, $10^{38.5}$ to $10^{41.5}$ erg/s for E and SO galaxies, and 10^{41} to 10^{45} erg/s for radio galaxies¹⁵. It thus seems

reasonable that BSOs are not a separate class of stellar objects, but are QSOs with small intrinsic radio luminosity.

Evidence for an Anisotropy in the Cosmic Ray Signal

COSMIC rays are one of the chief constituents of the physical universe but their origins are still not understood. Anisotropies in the cosmic ray signal should provide information toward the solution of these problems. This report presents evidence for an anisotropy in the cosmic rays centred around 0900 h sidereal time and between $+30^\circ$ and $+60^\circ$ declination.

The anisotropy has been observed with a cosmic ray telescope 30 miles south of Plattsburgh, New York (approximately 45° N, 74° W, and 400 feet above sea level).

Fig. 1. Sketch of silo laboratory indicating the position of the detector.

Fig. 2. Sidereal time histogram. Number of event per 90 min bin versus local sidereal time. Data were collected from August 1967 to June 1968 using a 50 gallon target. Over 3,000 events are plotted.

Fig. 3. Eastern standard time histogram. Number of events per 90 min bin versus eastern standard time. Data were collected from August 1967 to June 1968 using a 50 gallon target. Over 3,000 events are plotted.

The data consist of the clock times of muon events in a liquid scintillator and were collected between August 1967 and June 1968, and from December 1968 to June 1969 (Figs. 2, 5). This work is a continuation of earlier investigations with similar detectors.

The experiment is concerned with muons of moderate energy (less than 200 MeV) which appear and decay in the detector. The telescope consists of an abandoned Atlas F missile silo and a liquid scintillation counter surrounded by an anti-coincidence shield of plastic scintillator. The detector is about 120 feet below ground level. The experimental arrangement is similar to earlier experiments at the Catholic University, Washington, DC, the most important difference being the collimating effects of the silo (Fig. 1), approximately 180 feet deep and 50 feet in diameter. Directly above the detector, at a height of about 120 feet, are concrete doors two feet thick. The resolution of the telescope is estimated to be $\pm 15^\circ$ in right ascension and declination. The part of the sky visible to the detector extends approximately from $+30^\circ$ to $+60^\circ$ declination, and is swept once every 24 h. From August 1967 to June 1968, fifty gallons of liquid scintillator were used as the detector target. The liquid was contained in a 'Plexiglass' box 48 inches by 24 inches by 12 inches filled to within 1 inch of the top. From December 1968 to June 1969 eighty gallons of liquid scintillator, contained in a plexiglass box 48 inches by 24 inches by 24 inches filled to within 6 inches of the top, were used as the target. Thus there were two independent runs under somewhat different detector configurations. Moderate energy muons which appear and decay in the detector, and which satisfy the anti-coincidence requirement, are presumed to have been produced by a neutral particle in the cosmic rays.

The 'Plexiglass' tank is viewed by two 58 AVP photomultiplier tubes and is surrounded on all sides by an anti-coincidence shield of 3/4 inch plastic scintillator. The plastic scintillator is viewed by one 58 AVP and twenty-six XP1000 photomultiplier tubes. The two 58 AVP tubes viewing the liquid scintillator are run in coincidence with each other and in anti-coincidence with the twenty-seven photomultiplier tubes attached to the anti-coincidence shield.

Data are collected by a camera attached to an oscilloscope which are both triggered whenever an event in the detector has satisfied the coincidence and anti-coincidence requirements. A particle satisfying the anti-coincidence condition generates an electronic gate 6 μ s long which is delayed 0.3 μ s relative to the incident particle. If the incident particle decays during the time that the gate is open ($\mu \rightarrow e + V_e + V_\mu$) the oscilloscope and camera are triggered. The data consist of two pulses, the incident and the decay particles and EST of events. So far more than 8,000 muon-like events have been observed. The signal rates for the two runs were, on the average, 0.75 per hour and 1.75 per hour respectively.

The data are printed out in ninety-six 15 min sidereal and EST bins. The events in each bin are then combined into 90 min bins and histograms of the number of events per 90 min bin versus sidereal and EST are plotted. An event is assumed to be a muon and its decay electron.

The equipment is checked periodically by taking the rates of ordinary cosmic ray muons satisfying the coincidence and delayed coincidence condition with the anti-coincidence turned off. The background coincidence rates for the two runs averaged approximately 600 c.p.m. and 650 c.p.m. and the delayed coincidence, the number of stopping muons in the detector from ordinary cosmic rays, averaged approximately 1.5 per min and 3.0 per min respectively for the two detector configuration.

Data were collected with some shut downs, from August 1967 to June 1968 (Figs. 2, 3 and 4). There is a peak of 3.7 standard deviations in Fig. 2 between 0830h and 1000h local sidereal time. The probability of such a peak occurring by chance is less than one in four thousand (0.025 per cent probability of randomness). The same data plotted as a function of EST shows no peaks greater than 2.0 standard deviations which is to be expected because the sidereal clock gains roughly four min a day on the solar clock. In Fig. 4 the data are plotted in 60 min bins as a function of sidereal time. A peak of 3.9 standard deviations occurs around 0900 h local sidereal time. The probability of randomness is less than 0.01 per cent—that is less than 1 in 10,000.

Fig. 4. Sidereal time histogram. Number of events per 60 min bin versus local sidereal time. Data were collected from August 1967 to June 1968 using a 50 gallon target. Over 3,000 events are plotted.

Fig. 5. Sidereal time histogram. Number of events per 90 min bin versus local sidereal time. Data were collected from December 5, 1968, to June 1, 1969, using an 80 gallon target. Over 5,000 events are plotted.

Fig. 6. Eastern standard time histogram. Number of events per 90 min bin versus eastern standard time. Data were collected from December 5, 1968, to June 1, 1969, using an 80 gallon target. Over 5,000 events are plotted.

The second run began in December 1968. Fig. 5, the sidereal histogram of the number of events per 90 min bin, has a peak of 2.3 standard deviation between 0915 h and 1045 h local sidereal time. The same data plotted as a function of EST (Fig. 6) have no peaks greater than 1.8 standard deviations.

Because the anti-coincidence factor is estimated to be 500 to 1, one cannot rule out leakage muons from the cosmic ray background. The estimate is based on the measurement of the anti-coincidence factor using an external detector placed above and outside the box containing the telescope detector. This means that about 1/3 of the events are due to leakage muons from the cosmic ray background and could be responsible for the sidereal effect. The observed muon signal does indicate a strong dependence on sidereal time and the effect has persisted in the same area of the sky for two consecutive years and under somewhat different detector configurations. The reality of the anisotropy seems to be well established.

Plans are in progress to move the detector fifty feet deeper into the silo which should improve the resolution of the telescope. We are also making efforts to determine whether the muons are leakage muons or are produced in the detector by a neutral particle in the cosmic rays.

I thank Professor Clyde L. Cowan of the Catholic University for advice and assistance. This work was carried out under contract to the US Office of Naval Research. I also thank the Research Foundation of the State University of New York for two summer faculty fellowships and the State University College of Arts and Sciences, Plattsburgh, New York, for the use and maintenance of the silo laboratory.

Compositions of Garnets in Interstellar Dust

HUFFMAN¹ has shown that absorption bands in the optical spectra of the supernova in NGC 4496 correlate well with d-d bands of Fe³⁺ in yttrium iron garnet and Fe²⁺ in terrestrial almandine, Fe₃²⁺Al₂³⁺Si₃O₁₂. I have suggested² that the 4430 Å band in supernova spectra is a result of Fe³⁺ in a silicate matrix, the band being reminiscent of that marking the ⁶A₁(S)→⁴A₁E(G) transition

Fig. 1. A plot of B against a_0 for a series of garnets. SPESS, spessartine; GRO, grossular; AND, andradite; SCHORL, schorlomite.

in octahedral Fe^{3+} in andradite garnet, $\text{Ca}_3\text{Fe}_2\text{Si}_3\text{O}_{12}$. It is likely that interstellar garnets are silicate-based, and here I propose approximate formulae for these garnets based on the identification of two interstellar absorption bands, the energies of which can be related to garnet compositions.

The transitions ${}^6\text{A}_1 \rightarrow {}^4\text{A}_1, {}^4\text{E}(\text{G})$ and ${}^6\text{A}_1 \rightarrow {}^4\text{E}(\text{D})$ in Mn^{2+} and Fe^{3+} are field-independent^{3,4}, and the corresponding absorption bands are relatively sharp^{4,5}. The energies of these transitions, ν_1 and ν_2 respectively, are related to the Racah interelectronic repulsion parameters, B and C , by

$$\nu_1 = 10B + 5C \text{ and } \nu_2 = 17B + 5C$$

from which B and C can be measured if ν_1 and ν_2 can be determined from spectra⁵. The B values for metal ions in crystals are smaller than for free ions, and Jorgensen^{6,7} attributes this decrease in B to covalent bonding, in which metal d-electrons occupy a greater volume encompassing metal and anion. Jorgensen proposed that for a given cation, B is a measure of covalency: the smaller B is, the greater is the covalency. B values derived by Keester and White⁵ for Mn^{2+} in oxides and silicates show that there is reasonable correlation between B and covalency.

Table 1. SPECTRAL DATA FOR OCTAHEDRAL Fe^{3+} IN SILICATES (ν_1 , ν_2 AND B IN cm^{-1})

Silicate	Cube ion	Oct. ion	ν_1^*	ν_2	B
Spessartine	$\text{Fe}^{2+}\text{Mn}^{2+}$	Al^{3+}	23500	26900	490
Grossular	Ca^{2+}	Al^{3+}	23100	27000	555
Andradite	Ca^{2+}	Fe^{3+}	22850	26950	590
Schorlomite	Ca^{2+}	Fe^{3+}	22900	27000	590
Muscovite			22600	27300	670
Kyanite			22900	27000	585

* Except for muscovite, indicates average energy of ${}^4\text{A}_1(\text{G})$ and ${}^4\text{E}(\text{G})$ levels. B (free ion) = 930 cm^{-1} (ref. 9).

Recently, I determined⁸ B values for octahedral Fe^{3+} ions in a number of silicates, including garnets. Values of ν_1 , ν_2 and B are listed in Table 1, while a plot of B against a_0 (the cell edge) for garnets is shown in Fig. 1. Absorption bands marking ν_1 and ν_2 in grossular and andradite were identified earlier¹⁰, whereas bands corresponding to ν_1 and ν_2 for a spessartine are shown in Fig. 2. The two sharp peaks at $23,300 \text{ cm}^{-1}$ and $23,700 \text{ cm}^{-1}$

mark transitions to ${}^4\text{A}_1(\text{G})$ and ${}^4\text{E}(\text{G})$ levels separated by 400 cm^{-1} . Both components are also observed in andradite and schorlomite spectra, but the $22,700 \text{ cm}^{-1}$ band is much the stronger. The estimated error in B is $\pm 10 \text{ cm}^{-1}$.

Fe^{3+} -O distances will certainly increase with increasing a_0 , hence the corresponding decreasing trend in covalency (rising B) can be attributed to poorer d-orbital overlap. The parent Al-O distances in pyrope ($a_0 = 11.46 \text{ Å}$)¹¹ and grossular ($a_0 = 11.85 \text{ Å}$)¹² are 1.89 Å and 1.945 Å , respectively.

Schorlomite¹³ is a high-Ti andradite in which each octahedral cation has an average of 1.5 Al^{3+} or Ti^{4+} ions in the next-nearest-neighbour tetrahedral sites. These latter ions form bonds which are less covalent than those of Si, and hence nett charge on the oxygens increases and octahedral- Fe^{3+} -O bonds become more covalent. Substitution of Si ions therefore lowers the value of B .

Table 2. COMPARISON OF BAND ENERGIES IN Fe^{3+} SPECTRA (cm^{-1})

Andradite (oct. Fe^{3+})	Kimzeyite (oct. + tet. Fe^{3+})	Supernova 4496	Fe^{3+} coord. (this work)
26950*		26300	OCT.
	24100	24390	TET.
22700*	22700	22600	OCT.
		20600	TET.
	20600	20400	TET.
		19600 (Fe^{2+})	
		17500 (Fe^{2+})	
16700*	16700	16100	OCT.

* In increasing energy, mark transitions to ${}^4\text{T}_2(\text{D})$, ${}^4\text{A}_1, {}^4\text{E}(\text{G})$ and ${}^4\text{E}(\text{D})$ levels respectively.

The absorption spectrum of the garnet kimzeyite¹⁴, in which Fe^{3+} ions are located in both octahedral and tetrahedral sites, shows two bands in addition to the octahedral Fe^{3+} bands of andradite (Table 2). These bands, at $20,600 \text{ cm}^{-1}$ and $24,100 \text{ cm}^{-1}$, very likely mark transitions to the ${}^4\text{T}_2(\text{G})$ and ${}^4\text{A}_1, {}^4\text{E}(\text{G})$ levels in tetrahedral Fe^{3+} , and correspond to the $20,300 \text{ cm}^{-1}$ and $22,700 \text{ cm}^{-1}$ bands observed in spectra of tetrahedral Fe^{3+} in phlogopite¹⁵. A band at $\sim 16,700 \text{ cm}^{-1}$ marking transitions to ${}^4\text{T}_2(\text{G})$ levels is a characteristic feature of octahedral- Fe^{3+} spectra^{10,16}.

Fig. 2. Parts of absorption spectrum of a spessartine from Ceara, Brazil, showing bands corresponding to ν_1 and ν_2 .

The spectrum of SN-NGC-2713 (ref. 17), presented in Fig. 3, is similar to that of SN-NGC-4496 (ref. 18) except that a band is observed in the latter spectrum at 3800 Å and that the band at 4870 Å in the former is resolved into two components at 4850 Å and 4900 Å in the latter. By analogy with the bands in natural garnets, I would assign the 16,100 cm⁻¹ (6200 Å), 22,600 cm⁻¹ (4430 Å) and 26,300 cm⁻¹ (3800 Å) bands to transitions to the ⁴T₂(G), ⁴A₁E(G) and ⁴E(D) levels in octahedral Fe³⁺. The 20,600 cm⁻¹ (4850 Å), 20,400 cm⁻¹ (4900 Å) and 24,400 cm⁻¹ (4100 Å) bands can be assigned to tetrahedral Fe³⁺. The B-value for octahedral Fe³⁺ based on $\nu_1 = 22,600$ cm⁻¹ and $\nu_2 = 26,300$ cm⁻¹ is 535 cm⁻¹. Because the replacement of Si by other cations will increase rather than decrease the covalence of octahedral Fe³⁺-O bonds, it is likely that the interstellar garnet is an andradite in which a significant proportion of Si⁴⁺ ions have been replaced by Fe³⁺ and possibly Al³⁺ ions. The envelope marking transitions to the ⁴A₁E(G) levels in supernova spectra is most similar in energy and shape to that of an andradite or a Si-substituted andradite, while the band half-widths measured earlier² imply substitution of Si by other larger cations. It would therefore appear that the Fe³⁺ ions are located in octahedral and tetrahedral sites in the same crystal.

Fig. 3. Spectrum of supernova in NGC 2713 in optical region¹⁷.

There is no continuous change in composition between almandine-type and andradite-type garnets¹⁹. Huffman¹ has compared the interstellar bands at 19,600 cm⁻¹ (5100 Å) and 17,500 (5700 Å) to spin-forbidden bands of 8-coordinate Fe²⁺ in almandine. The extinction coefficient of the 19,700 cm⁻¹ band in terrestrial almandine is approximately five times smaller than that of the 22,700 cm⁻¹ band in andradite, which in turn is ten times smaller than that of the 22,700 cm⁻¹ band in schorlomite²⁰. Hence, supernova in NGC 2713 and NGC 4496 contain considerably more almandine than andradite-type garnet.

Based on ionic radii and known chemistry in oxygen and garnet systems²¹, Al³⁺ is most likely to substitute for Si⁴⁺, followed by Fe³⁺ and then Ti⁴⁺. Assuming a 25 per cent deficiency of Si⁴⁺ ions in tetrahedral sites and that there are no Al³⁺ ions in octahedral sites, an approximate formula is Ca₃(Fe³⁺Ti⁴⁺)₂(Si_{1.25}Al_{0.75}Fe³⁺)O₁₂. To balance charges, 0.8 Ti⁴⁺ ions are required in octahedral sites, while band intensities indicate that the ratio of tetrahedral-Fe³⁺ : octahedral-Fe³⁺ is not likely to be as low as 1:10. Hence the formula reduces to

If the current assignments of bands in supernova spectra are correct, interstellar dust contains two garnets,

one of the almandine-type and the other a substituted andradite with appreciable amounts of Fe³⁺ and, possibly, Al³⁺ in Si⁴⁺ sites.

Five New Pulsars

FIVE new pulsars have been discovered in a systematic search at low galactic latitudes, using the Mark I radio telescope at Jodrell Bank, and a radio frequency of 408 MHz. A total of 431 independent points were observed (many of them more than once) at integral degrees of galactic latitude and longitude, including all such points with latitude $-1, 0$, and $+1^\circ$ and longitude $11^\circ \leq l \leq 125^\circ$. The beamwidth of the telescope to half power was $0^\circ.8$.

The system was designed to detect periodic signals in the range of periods $0.2 < P < 3.6$ s. The outputs of two receivers, each with 4 MHz bandwidth and detecting the two hands of circular polarization, were combined, and the detected signal was sampled digitally every 50 ms over a period of 13 m 39 s, that is for 2^{14} samples. Periodic signals were found by a process amounting to cross correlation of this digital signal with pulse trains of duty cycle 25 per cent. The system was therefore equally sensitive to pulsars with a large range of dispersion measure, which would be expected to lengthen the pulses in the wide receiver bandwidth. For pulsars with dispersion measure up to $500P$ cm⁻³ pc, and lying close to the beam centre, the limiting flux density is 0.02×10^{-26} W m⁻² Hz⁻¹, and it is unlikely that any pulsar stronger than this limit within $10'$ arc of the positions observed has escaped detection.

The new pulsars have been studied at 406, 408, 410 and 610 MHz to obtain information on the dispersion measure, pulse shape and period. The data and standard errors are given in Table 1. The barycentric periods have been calculated using the quoted positions, and the errors in period refer only to the uncertainty in timing measurements. Two of the new pulsars, JP 2003 and JP 2319, have periods in excess of 2 s; only one other known pulsar (NP 0527) has a longer period. JP 2003 has an unusually short pulse, the equivalent width (pulse energy divided by peak flux density) being only 1 per cent of the period. JP 2319 is situated only $1^\circ.5$ from the supernova remnant

Cas A, but it is unlikely that the objects are physically associated; the age and distance of Cas A (300 yr, 3.5 kpc) would imply that the pulsar was ejected from the supernova at the velocity of light.

Fig. 1. A computer graphical output showing the integrated pulse profiles of JP 1858 at 408 MHz and 610 MHz. The difference in position of the pulse is due to the dispersion and corresponds to 290 ms plus an integral number of periods. The effective resolution (due to time constant, sample length and dispersion in the receiver bandwidth) is indicated on each trace by a horizontal bar. The unusual width and extended trailing edge of the pulse at 408 MHz is thought to be caused by scintillation broadening.

The most interesting of the new pulsars is JP 1858, which has the highest dispersion measure of any known pulsar. The distance, based on this dispersion measure and an assumed mean electron density $\bar{n}_e = 0.05 \text{ cm}^{-3}$ is 8 kpc. It thus lies at about 5 kpc from the galactic centre, presumably in an inner spiral arm. Fig. 1 is a

a consequent scatter in the arrival time of the pulse at a single frequency. A simplified argument suggests that scintillation should produce an exponential tail to the observed pulse with a decay time constant that increases with the square of the dispersion measure and the fourth power of the wavelength. A similar effect has been reported³ for the Crab pulsar (NP 0532) where the extremely short natural pulse makes scintillation broadening apparent at a moderate dispersion measure. Assuming the scale of the effect indicated by these two pulsars is characteristic of the interstellar medium in general, scintillation broadening should be detectable by measurement of high dispersion pulsars at a number of frequencies, and should provide valuable further information on the clumpiness of the ionized interstellar medium.

Scintillation broadening can be expected to limit the sensitivity of searches for high dispersion pulsars, particularly those of short period. As an example it is interesting to consider the effect on the Jodrell Bank and Molonglo searches at 408 MHz (which together have discovered 38 of the 55 known pulsars). The pulse shapes of JP 1858 indicate that at 408 MHz the broadening is given by

$$t \text{ (ms)} \approx \left(\frac{dm}{50} \right)^2$$

where dm is the dispersion measure in $\text{cm}^{-3} \text{ pc}$. On this basis, the sensitivity of 408 MHz searches would deteriorate rapidly for dispersion measures greater than 300 or $1,000 \text{ cm}^{-3} \text{ pc}$ for periods of 0.1 s or 1.0 s respectively. Hence in searches carried out so far at 408 MHz, scintillation broadening is probably less important than widening of the pulse by dispersion in the receiver bandwidth as a cause of loss of high dispersion short period pulsars. As scintillation broadening increases with the square of the dispersion measure, however, and cannot be corrected for by techniques analogous to "dispersion removing", it may prove a serious obstacle to extending pulsar searches to remote regions of the Galaxy.

Mean flux density at 408 MHz $\text{W m}^{-2} \text{ Hz}^{-1} \times 10^{-26}$	$0.04 \pm 30 \text{ per cent}$	$0.03 \pm 30 \text{ per cent}$	$0.02 \pm 30 \text{ per cent}$	$0.02 \pm 30 \text{ per cent}$	$0.02 \pm 30 \text{ per cent}$

graphical output from the computer showing 4 h 45 m integration of pulses from JP 1858 at 408 and 610 MHz. The difference in position of the pulse on the two traces is due to dispersion, and corresponds to 290 ms plus 8 complete periods. It will be seen that the observed pulse is considerably longer at 408 MHz than at 610 MHz. At 408 MHz the bandwidth used in this measurement was 1.1 MHz giving a dispersion widening of 55 ms. At 610 MHz the 4.3 MHz bandwidth gives a dispersion widening of 64 ms. At each frequency the analogue time constant was 10 ms and the digital sample interval was 20 ms. Thus the effective resolution at 408 MHz is marginally better than at 610 MHz.

The natural pulse width of typical pulsars depends very little on frequency^{1,2} and we suggest that this unusually wide asymmetric pulse at 408 MHz is a result of scintillation broadening made apparent by the very large dispersion measure. Irregularities in the ionized interstellar medium give rise to multiple path propagation and

Lake Toba, Sumatra, and the Origin of Tektites

KAYSING suggested recently¹ that Lake Toba, Sumatra, Indonesia, was a possible source area for the Australian group of tektites. This suggestion was based on extrapolation from the observation of McColl and Williams² that the "majority of australite localities in south central Australia are concentrated along a line extending north-westwards.... A second subparallel line may exist in the west of South Australia, separated from the main line by an extensive tract of australite-deficient country". They consider that these lines represent primary distribution patterns, and Kaysing¹ suggests that suitable assumptions about ejection angles and allowance for the Earth's rotation "brings the intersection of the infall lines to Lake Toba".

Lake Toba, the largest lake in Indonesia, is one of the largest terrestrial features ascribed to volcanic action. The lake is 87 km long (the depression within which the lake occurs is 100 km long) and 31 km wide³. It is surrounded by a vast deposit of acid volcanic material, interpreted as welded tuff or ignimbrite, covering an area of 25,000 square km, with a volume of 2,000 cubic km⁴. This forms one of the largest occurrences of this type of rock and is matched in volume only by the large welded tuff sheets of the central North Island of New Zealand, the type locality for ignimbrite⁵. The consensus among geologists who have investigated Lake Toba is that it is a volcano-tectonic depression, which subsided after paroxysmal eruptions (Nuée ardente type) of acidic material from an underlying magma chamber. Westerveld⁴, in particular, is convinced of the "great parallelism between volcanic phenomena on Sumatra and in Northern New Zealand" and Williams⁶, Cotton⁷, and Ross and Smith⁸ have drawn similar conclusions. Acidic volcanic rocks, similar to those at Lake Toba, but on a reduced scale, occur widely in Sumatra, and in many other parts of the circum-Pacific region⁸. They seem to be an integral part of the calc-alkaline association of volcanic rocks associated with dipping seismic zones and deep trenches, although they are restricted to areas where crustal thickness exceeds about 25 km.

Is Lake Toba a potential source region for tektites? Volcanic theories for the origin of tektites have long been in disrepute⁹, principally because the observed distribution is too extensive (up to 4 per cent of the Earth's surface if the microtektite occurrences¹⁰ are included in the strewnfield) to be accounted for by eruptions from volcanoes. Thus Lake Toba would need to be an impact feature, because only meteorite, cometary or asteroidal impacts provide sufficient energy to account for the vast south-east Asia strewnfield. Lake Toba does not seem a particularly suitable candidate for an impact site. It is not circular, but elongated. The welded tuffs surrounding Toba are similar to other areas of undoubted volcanic origin in the circum-Pacific orogenic regions, and differ only in extent.

A decisive test is available from a comparison of the chemical composition of the welded tuffs with that of australites. The available data are collected in Table 1. The Toba analyses are old but probably reliable, and they agree with analyses of other welded tuffs. The central North Island ignimbrites generally have larger amounts of silica, but have similar contents of diagnostic elements such as magnesium¹¹, and individual matching analyses can be found¹².

An average of twelve australite analyses^{13,14} from localities extending from Charlotte Waters, NT, to Florieton, SA, along the line established by McColl and Williams² is given in column 5, Table 1. If the lake is the tektite source the compositions of the tuff and the tektites should be identical. It is clear from a study of the data in Table 1 that they are not. Particularly critical elements in this comparison are magnesium,

sodium and potassium. The australites contain more than twice as much magnesium and about half the sodium and potassium content of the welded tuffs. There is also a marked difference in the silica content. In order to ascertain whether these differences are dependent on silica content or sampling, I have made a comparison with other australites of similar silica content to the Lake Toba material. These comparisons are given in columns 6-9, Table 1, where typical australite analyses off the McColl-Williams line, but with silica contents of about 70 per cent, are listed. These analyses are again dissimilar to the Lake Toba material particularly for the critical elements magnesium, sodium and potassium.

These differences parallel those between the chemistry of tektites and terrestrial igneous rocks as has been repeatedly pointed out¹³⁻¹⁶. The chemical and isotopic composition is consistent with a parent material resembling terrestrial sedimentary rocks¹³⁻¹⁶.

The recent chemical, isotopic and age results from the lunar rocks¹⁷⁻¹⁹ show such a wide divergence from the tektite data as to make a lunar origin for tektites very improbable. It is thus necessary to locate another source of the south-east Asian strewnfield. The criteria for such a search have been discussed²⁰ and would be satisfied by cometary impact on shaly sandstones of Mesozoic age. There is, however, no *a priori* case for considering Lake Toba as a potential source area.

Stratigraphy of the Beacon Supergroup between the Olympus and Boomerang Ranges, Victoria Land, Antarctica

In the summer of 1968–69 a geological expedition from Victoria University of Wellington examined the Beacon supergroup over an area of 3,500 km² between the Olympus and Boomerang ranges (Fig. 1). In this area the Beacon supergroup comprises as much as 2,300 m of flat-lying non-marine sediments from Devonian or older to Triassic in age. The season's work contributed to the regional geology in two ways: abundant Devonian freshwater fish remains were discovered and collected, thus extending the known geographic distribution and variety of the fossil assemblage; and a thin sequence of glacial beds of Late Palaeozoic age were found to be widespread throughout the area. Data from the measurement of thirty detailed stratigraphic sections have also led to considerable refinement of Beacon supergroup nomenclature (Table 1).

Harrington¹ subdivided the Beacon strata in southern Victoria Land into the Taylor and Victoria groups (Table 1). The sediments of the Taylor group are mostly texturally mature, exhibit only rare carbonaceous matter and contain Devonian fish and other fossils in the higher strata. By contrast, the Victoria group contains a heterogeneous assemblage of rocks which are texturally less mature and contain an abundance of carbonaceous material in which the *Glossopteris* flora may be present in the lower part and the *Dicroidium* flora in the upper part.

The Taylor group rests on the Kukri surface (Kukri peneplain²), a widespread surface cut in Pre-Cambrian–Lower Palaeozoic igneous and metamorphic rocks. The upper limit of the group is the Maya erosion surface¹. The lowest Taylor group formation in the area studied, the New Mountain sandstone, is a light-coloured cross-bedded quartzose sandstone, with local pebbly sandstone, cyclic siltstone and mudstone and breccio-conglomerate members in the lower part (Table 1). The formation decreases

in thickness northward from 220 m at Mt Handsley to 46 m near Mt Boreas (Fig. 1). The New Mountain sandstone is truncated by a widespread and previously unrecognized erosion surface, here named the Heimdall erosion surface. The overlying Altar Mountain formation, which is 162 m thick at the type section (McElroy at the Mar de Plata symposium, 1967), consists of a 30 m thick Odin Arkose member followed by a cyclic, extensively burrowed sequence of quartzose sandstone and maroon-green siltstones. The two succeeding formations comprise chiefly quartzose sandstone. The 385 m thick Arena sandstone is largely a buff-coloured slope-forming unit, in contrast to the overlying Beacon Heights orthoquartzite, which forms prominent white cliffs more than 300 m high. The Beacon Heights orthoquartzite passes gradationally up into a red and green siltstone sequence, the Aztec siltstone. The latter formation thins northward from 138 m in the Boomerang range to 40 m at Aztec Mountain. The abundant well preserved fish remains in this unit are discussed.

Apart from the Permian *Glossopteris* floras in the lower part of the Victoria group the only fossil material on record in southern Victoria Land for many years were Devonian freshwater fish remains found in erratics, near Granite Harbour³. In the summer of 1957–58, however, Warren², a geologist with the trans-Antarctic expedition, collected fragmentary fish remains (fossil descriptions by White⁴) from five localities in southern Victoria Land. One of the aims of the 1968–69 expedition was the collection of additional fossil fish material. Warren's locality in the northern Boomerang range (near Alligator Peak) was relocated and extensive collections were made. A considerable number of new localities were discovered and fossil material recovered from these included jaws, teeth, skulls, dermal plates and fin spines. These fossils represent the best preserved and most varied Devonian fish yet found in Antarctica. At one locality in the northern Boomerang range the fossil skeletal elements occur in such abundance as to form extensive bedding plane pavements. The largest and best preserved skeletal elements are usually concentrated in a few beds, each only a few inches in thickness. Smaller and much fragmented material is scattered by reworking through the greater part of the formation. The most rewarding localities were found in the southern part of the Olympus–Boomerang range area where the Aztec siltstone is thickest and siltstones are predominant over interbedded sandstones.

A Devonian age for the Aztec fish fauna is favoured by all authors. Woodward³ assigned it to the Upper Devonian, and White⁴ supported an Upper Middle Devonian age. Matz and Hayes⁵ regarded them simply as Devonian, and McElroy cites a Middle or preferably Upper Devonian age (Mar de Plata symposium). The only associated fossil material in the Aztec siltstone is a microflora of eight species (dated as lower Upper Devonian) from a horizon above the fish beds and near the top of the formation at Aztec Mountain⁶. The only other known Devonian fish material from Antarctica is a single plate of an arctolepid from the Horlick Formation of the Ohio Range⁷, which is Lower Devonian in age.

Harrington's¹ division of Beacon strata into Taylor and Victoria groups was based largely on the meagre data then available from Aztec Mountain, Maya Mountain and Mt Weller^{8,9}. He proposed the name Maya erosion surface for the disconformity between the Devonian Aztec siltstone and Per-

mian Weller coal measures. As did earlier authors, Harrington drew attention to a glacial strata in the Devonian to Permian succession farther south in the Transantarctic Mountains and ascribed their absence in the Taylor Glacier area to non-deposition of glacial sediments on the glacially cut Maya erosion surface. Harrington correlated the disconformity at the base of glacial sediments of southern Transantarctic mountain localities¹⁰ with the disconformity (his Maya erosion surface) between the Aztec siltstone and Weller coal measures in the Aztec Mountain area.

As a result of the 1968-69 expedition it is now known that glacial beds are present in the Aztec and Maya Mountains sections and other localities in the Olympus-Boomerang ranges. The glacial beds (for which the name Metschel tillite is proposed) are disconformable on Aztec siltstone. Widespread erosion before the deposition of the Weller coal measures has removed the greater part or all of the glacial beds in many localities, destroyed the erosion surface at their base and cut down into the underlying Aztec siltstone. It was this upper disconformity that Harrington believed to be of glacial origin and for which he proposed the name the Maya erosion surface. We believe that the term Maya erosion surface is better reserved for the disconformity at the base of the glacial beds in the area of the Aztec-Maya Mountains. For the disconformity at the base of the Weller coal measures the name Pyramid erosion surface is proposed.

The lower boundary of the Victoria group is placed at the Aztec siltstone-Metschel tillite contact (= Maya erosion surface) where this exists, or the Aztec siltstone-Weller coal measures contact (= Pyramid erosion surface) where the Metschel tillite and Maya erosion surface have been eroded.

The name Metschel tillite is proposed for the glacial sequence of tillite, varvoid siltstone and associated stratified sediments. The formation is 27 m thick at Mt Metschel but reaches a maximum thickness of 38 m in the Boomerang range further to the south (Fig. 1). The tillite is usually massive with a grey-green sandy matrix in which scattered granitic, gneissic and metasedimentary clasts up to 1.5 m across occur. Large scale slumps are common in the stratified beds. The lower contact of the formation, the Maya erosion surface, is clearly disconformable to the north. At Aztec Mountain the surface bears a NW-SE oriented pattern of smoothly rounded elongate groove and ridge structures, possibly of glacial origin. To the

south, the Metschel tillite-Aztec siltstone contact is not as clear and requires more detailed investigation.

The Weller coal measures, which overlie the Pyramid erosion surface, consist of 170 m of cross-bedded carbonaceous sandstone and siltstone, with minor conglomerate lenses. Individual seams of bituminous to anthracite grade coal range up to a metre thick. The lower strata tend to be arkosic and include a basal conglomerate up to 15 cm thick, with clasts petrographically similar to those in the Metschel tillite, even where the tillite has been completely eroded. Leaves of *Glossopteris* and *Gangamopteris* indicate a Permian age for this formation.

McElroy (Mar de Plata symposium) proposed the name Feather conglomerate for 215 m of conglomerate and sandstone that overlie Weller coal measures at Mt Feather. We examined this formation at Mt Fleming and Portal Mountains and restrict the name to the lower conglomeratic beds. Thus the redefined Feather conglomerate is approximately equivalent to the unnamed 160 m thick middle Permian unit of Pinet, Matz and Hayes¹¹.

The name Fleming formation is proposed for 45 m of coarse, cross-bedded orthoquartzite and interbedded khaki to green siltstone that conformably overlies the redefined Feather formation at Mt Fleming. The Fleming formation is believed to be equivalent to the unnamed upper Permian unit of Pinet, Matz and Hayes¹¹.

The Lashly formation, youngest unit of the Victoria group, consists of 300 m of sandstone, shale and carbonaceous bands at the type section on Mt Feather (McElroy, Mar de Plata symposium). Similar strata were found near the summits of Mt Fleming and Portal Mountain. Plant microfossils collected from this formation at Mt Feather are probably late Middle Triassic⁶.

This subdivision of the Beacon supergroup into Taylor and Victoria groups has been firmly established. The nature of their contact is better understood following the discovery of Metschel tillite and the Maya and Pyramid erosion surfaces in the Aztec Mountain area. The Beacon section in the area studied is therefore more complete than previously thought and more akin to Devonian-Triassic successions farther south in the Transantarctic Mountains^{10,12}. Four major erosion surfaces, two previously unrecognized, are now known to exist in Beacon supergroup rocks between the Olympus and Boomerang ranges. Furthermore, the Aztec siltstone and its excellently preserved Devonian fish are now known to be distributed throughout the western part of this area. The formation

has yet to be reported beyond this area. Fossil fish collected during the 1968–69 field season have been sent to Dr A. Ritchie of the Australian Museum, Sydney^{13,14}. His comparison of Antarctic material with Devonian freshwater fish of Australia should lead to greater understanding of the similarities and differences between the faunas of the two continents and a refinement in the known geographic distribution of taxa in this fossil group.

We thank the Victoria University of Wellington and the University Grants Committee for financial help and Dr P. J. Barrett for discussions.

Some Non-linear Phenomena of Capillary Wave Propagation

STUDY of the interaction of nonlinear waves on a liquid surface is of considerable interest¹ because it may help to explain a great number of phenomena in wave dynamics of the sea. It is also relevant to capillary waves and the modelling of the nonlinear wave processes for dispersive media, which is of interest in nonlinear optics and electro-dynamics. The study of nonlinear capillary waves is also important for capillary hydrodynamics.

This report deals with some experiments on the propagation of nonlinear capillary progressive waves. The theory of nonlinear progressive capillary waves has been developed in a number of papers^{2–5}, but relatively little experimental work has been done on this subject^{6–7}. We have observed the second and higher harmonics which were generated during the propagation of capillary waves on a water surface and have noted the change in the form of oscillation in these waves.

We used a very simple device for the experiment. The almost plane capillary waves were generated by a light aluminium stick attached to a sound dynamic diffusor. The width of the light aluminium stick is approximately 10λ (for the low frequencies). The measurements were carried out at no more than $15\text{--}20\lambda$ from the aluminium stick and the diffraction effects were negligible. The homogeneity of the capillary wave field was controlled by means of stroboscopic light.

The measurements were carried out with technical water, which is a weak electrolyte. The device used as a receiver for the capillary waves consisted of a thin steel wire touching the surface of the water, which acted as the first electrode, and a copper plate as the other electrode plunged into the water underneath the wire. The distance between the copper electrode and the wire was 1.5 to 2 cm. A constant polarization voltage (10 V) was applied between the wire and the plate. In the propagating capillary wave the wire, which was 0.5–0.7 mm diameter, was periodically immersed in the water. The resistance between electrodes changed and as a result an alternating voltage emerged. The resistance of the waterlayer between the end of the wire and the other electrode was $\geq 20\text{ k}\Omega$. Thus the current between electrodes was less than 0.5 mA. The dependence of the probe current on the plunging depth was measured (static method). The current depended linearly on the depth, starting at $0.1 + 0.2\text{ mm}$. By means of the selective amplifier it was possible to carry out a harmonic analysis of the wave, to single out the second, third and higher harmonics successively. The amplifier had a broad frequency band so it was possible to observe the oscillating form of the surface.

The measurements were carried out at frequencies of 40–300 Hz and for amplitudes $10^{-1}\text{--}10^{-2}\text{ cm}$. The non-dimensional number $M = V/\lambda = 2\pi ac$ was of the order of 1. Here v is the oscillating velocity, c_1 is the phase velocity of the capillary waves, a is the displacement amplitude and λ is the capillary wavelength. The dispersive number for capillary waves is given by $D = (C_2 - C_1)/C_1 = 0.26$, where C_2 is the phase velocity for the wave with double the frequency. Our measurements therefore applied to the range $M \gtrsim D$ and dispersion could not effectively prevent the developing of nonlinear effects.

Fig. 1 shows the oscillogram of the second harmonic amplitude (logarithmic scale) and its dependence on the distance from the wave source; the frequency of the source was 200 Hz. The sharp upper lines are the distance marks at an interval of 1.5 cm. There are oscillations of the second harmonic amplitude caused by the differences between the phase velocities of the first and second harmonics. This is typical of nonlinear waves in the dispersive medium. Such nonsynchronous effects are well known in nonlinear acoustics (see for instance ref. 8) and in nonlinear optics⁹. It follows from the theory that the oscillation period Δ_{2f} is given by $\Delta_{2f} = 2\pi(2k_1 - k_2)^{-1}$, where k_1 and k_2 are the wave numbers for the first and second harmonics respectively. For capillary waves with their dispersive law we have $\Delta_{2f}/\lambda = 2.42$. Table 1 shows the values of Δ_{2f} for different frequencies very close to the experimental values. The experimental values λ , c and Δ_{2f} were obtained with our experimental set up and the measurements of λ and c were carried out with a phase interferometer on

Fig. 1.

Fig. 2.

the Lissajous figures with an accuracy of 2–3 per cent. We deduce that the weak current between electrodes has no noticeable influence on σ . This phase interferometer proved to be very dependable. With the measured value of λ and c , σ was calculated. The difference between experimental and theoretical values of σ is small and on the low frequencies no more than 5 per cent. As can be seen from Table 1 the difference between theoretical and experimental values of Δ_{2f} is small and even on the high frequencies the error in Δ_{2f} is only ~ 10 per cent.

Table 1. THEORETICAL AND EXPERIMENTAL RESULTS OF THE VELOCITY C_1 , WAVELENGTH λ AND THE OSCILLATORY PERIOD Δ_{2f} OF THE SECOND HARMONIC

* At the low frequencies the theoretical values c_1 , λ , k , were calculated with formulae for the capillary wave. The capillary waves occur when $K > (g/\sigma)\lambda$ where K is the wave number, g is the Earth's acceleration, σ is the density and σ is the surface tension coefficient. For water $(g/\sigma)^{1/2} = 3.65$ and at frequencies as low as 80 Hz the gravitation force is important.

The nonlinear distortion of the capillary wave is rather strong. For instance, at 80 Hz ($\lambda = 0.41$ cm) and for $a \approx 10^{-2}$ cm at the first maximum (a is the so called mathematical wave amplitude equal to the value half way between maximum and minimum amplitudes) the amplitude of the second harmonic was as large as 13–15 per cent as that of the first one.

We were unable to observe the stationary form of the wave profile which was predicted theoretically⁵. At every point on the surface the profile was stationary in the course of time; however, at different intervals from the source it varied periodically with the distance from the source. Fig. 2 shows the oscillograms of the wave profile at $a = 8.7 \times 10^{-2}$ cm and a frequency of 80 Hz. In Fig. 2a we see the profile form which is almost a back to front saw-tooth wave (the foremost time front is shallow but the back front is steep). As the distance becomes greater the form gets transformed and becomes the counter-form to that in the theory⁵ (see Fig. 2b). The further displacement of the receiver leads to a "shock" (saw-tooth) capillary wave (Fig. 2c) with a steep front, and then to the form predicted in ref. 5 (Fig. 2d). The latter form is in good agreement with theoretical predictions⁵ if we take into account the values of a/λ . Displacing the receiver further again leads to the counter form saw-tooth wave (Fig. 2a)—"shock"—and to the form predicted in ref. 5. The period of such transformations is approximately 3λ . These experiments were carried out at $M = 1.3 > D$ and in these conditions, even in the case of a dispersive medium, the form of the saw-

tooth wave appeared. Because of dispersion this wave is transformed quickly to other profiles.

It is difficult to carry out similar experiments for electromagnetic waves in the optical part of the spectra. We may expect, however, that for optical waves a saw-tooth profile will be formed if the non-dimensional numbers M and D are related roughly as in our experiments with capillary waves.

Orientation of Vacuum Condensed Overgrowths through Amorphous Layers

A VERY striking phenomenon regarding the interaction between substrate and overgrowth atoms during vacuum deposition was recently reported by Distler *et al.*^{1,2}. This phenomenon is the oriented nucleation of gold on NaCl substrates precoated with amorphous carbon layers below a critical thickness. Distler *et al.* interpreted their results in terms of long-range active centres^{3,4} which are present on the substrate surfaces in densities corresponding to that of gold nuclei and concluded that "oriented crystallization of gold through carbon films indicates that neither the microgeometry of the surface nor the fit in lattice parameters of NaCl and gold are of decisive importance for epitaxy"².

In view of the great significance of these observations, Chopra⁵ carried out careful and systematic experiments in an attempt to confirm them. His results, however, did not agree with the observations of Distler *et al.* Barna *et al.*⁶ studied the growth of ZnS and PbS on NaCl substrates that were precoated with SiO or C layers of various thicknesses. Although these are not strictly comparable with the Au/C/NaCl system, it is worth mentioning here that PbS grew only partially oriented on air-cleaved NaCl precoated with ~ 130 Å of C.

I have carried out some experiments which confirm the observations both of Distler *et al.* and of Chopra. Various corresponding portions of air cleaved and vacuum cleaved ($\sim 10^{-8}$ Torr) NaCl and KCl single crystals at $\sim 200^\circ$ C were simultaneously coated with carbon layers of various thicknesses in an ultra high vacuum system (10^{-7} to 10^{-6} Torr during carbon evaporation). Gold was then deposited at a rate of ~ 2 Å/s on these substrates at 340° C while certain portions of bare surface and of carbon coated regions were screened. Thin (~ 20 Å) as well as thick (~ 100 Å) gold films were deposited on every region of the substrates. A detailed account of the results will be published at a later stage and only the most important aspects will be mentioned here.

Fig. 1 shows the electron micrograph and diffraction patterns of a thick (~ 1000 Å) gold film that was deposited on the region of a vacuum cleaved NaCl crystal which carried the boundary between a 105 Å (left) and a 150 Å

(right) carbon coating. It is to be noted that polycrystalline gold film on the thicker carbon layer displays agglomerated polycrystalline grains whereas the perfectly single crystalline gold film on the thinner carbon layer is much more uniform and continuous with many microtwins. Similar results were obtained on the vacuum cleaved KCl crystal. The variation of surface mobility of gold nuclei on successively thicker carbon layers seems to be an important factor in determining the structure. The initially nucleated gold deposit on the left hand region of vacuum cleaved NaCl, shown in Fig. 1, revealed completely randomly oriented gold nuclei, as shown in the diffraction pattern in Fig. 2. It is only during the further growth and coalescence of nuclei that a perfectly oriented gold film results. The thicknesses of the carbon layers were determined by means of an oscillating quartz crystal microbalance. Fig. 3 shows an electron micrograph of a portion of the 105 Å carbon layer screened during gold deposition. The diffraction pattern showed that this carbon film was amorphous and from Fig. 3 it is clear that the film was without large discontinuities or holes. These results therefore confirm the controversial observations of Distler *et al.* It is also noted that the transition from single crystalline to polycrystalline gold deposits occurs over a rather small range of carbon layer thicknesses which makes the critical carbon thickness a very sensitive parameter for quantitative experiments on this phenomenon.

The gold films that were grown on the carbon coated portions of air cleaved NaCl and KCl crystals were all polycrystalline. Not even on 45 Å carbon layers could thick single crystalline gold films be obtained, although

Fig. 1. Transmission electron micrograph and diffraction patterns of ~1000 Å gold film on the region of a vacuum cleaved NaCl crystal precoated with relatively thin (left) and slightly thicker (right) carbon layers. $\times 16,000$.

Fig. 2. Transmission electron diffraction pattern of initially nucleated gold deposit (~20 Å) on the left hand region of vacuum cleaved NaCl shown in Fig. 1.

Fig. 3. Electron micrograph of a corresponding portion of the carbon layer on vacuum cleaved NaCl to the left of Fig. 1. $\times 24,000$.

Fig. 4. Transmission electron micrograph and diffraction pattern of ~1000 Å gold film on air cleaved NaCl precoated with a carbon layer corresponding to that on the left of Fig. 1.

strong preference for the (001) parallel orientation occurred as may be seen from Fig. 4. In fact, the electron micrographs of the gold films revealed large patches of (001) orientation mixed with equally large areas of polycrystalline orientations. Above 150 Å carbon layer thickness this patchlike nature disappears and the thick gold film becomes completely polycrystalline. The latter results therefore confirm Chopra's observations. It is believed that he must have used air cleaved substrates because he quoted them merely as having been "freshly cleaved" and not as vacuum cleaved. It is possible that the air cleaved surfaces are either already covered with a thin amorphous water layer or that the surface layer of the crystal is altered in such a way that it does not contribute to long range forces to the same extent as does the parent surface layer of a vacuum cleaved crystal. This could possibly be the case, for example, when the chlorine ions of the parent surface layer are replaced by hydroxide ions, leading to a relatively smoother surface potential⁷.

I thank my colleagues for fruitful discussions and Mr J. C. Lombaard for his assistance with the electron microscope investigations.

High Energy Photoelectron Spectroscopic Study of Carbon Fibre Surfaces

KNOWLEDGE of the internal structure of carbon fibres, which are derived from polyacrylonitrile and rayon by carbonization in special conditions¹⁻³, has increased significantly in the past few years. Investigations using small-angle and conventional X-ray diffraction⁴⁻⁹, electron diffraction^{6,10,11}, intercalation with caesium¹², helium density determinations⁶, polarized light microscopy¹¹, and high-resolution electron microscopy^{6,13}, have established that the carbon layers form long (greater than 100 nm) ribbons with preferred orientation of the layers parallel to the fibre axis. A number of these parallel ribbons form a so-called microfibril⁶, the average thickness (or stack size) of which, in fibres that have been heat treated to 1,300 K or beyond, is in the range 3-10 nm. The microfibrils are believed to be wrinkled and bent^{6,9} and they may even be twisted to form rather inaccessible voids. Within the layers, the C-C bond distance⁹ is 1.416 ± 0.007 Å, and for this, and other reasons⁶, the bonding is believed to involve only sp^2 hybridized carbon atoms. There is no evidence of cross-linking between the layers (which contain a few per cent of structural defects⁹) perpendicular to the axis of the microfibrils.

The commercial exploitation of carbon fibres hinges on the discovery of effective methods of increasing the interfacial shear strength between the cylindrical fibre surface and the compatible material with which they are formed into composites. Knowledge of the atomic structure of the exterior surfaces of carbon fibres is therefore essential, and the surface structures have recently been studied by physical adsorption and chemisorption of gases¹⁴. Reflexion electron diffraction¹¹ has also been used, for the structures thus revealed refer to depths of less than 100 nm from the surface. We describe here a new approach to the direct study of surface structures: the use of high energy photoelectron spectroscopy¹⁵

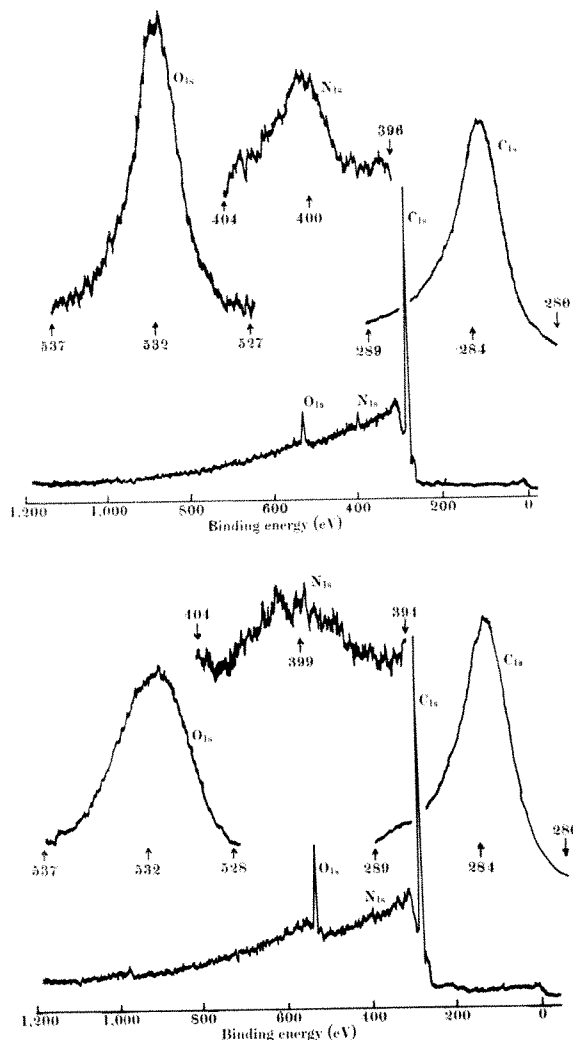

Fig. 2. High energy photoelectron spectra of nitrogen 1s, oxygen 1s, and carbon 1s electrons in Courteille carbon fibre, baked at approximately 1,300 K in nitrogen (type b or type II)—top spectra; and spectra of the same fibre subjected to oxidation (type c)—bottom spectra. There is an appreciable increase in oxygen bound to the surface following oxidation.

Fig. 1. High energy photoelectron spectra of nitrogen 1s, oxygen 1s, and carbon 1s electrons in oxidized Courteille carbon fibre (type a). The shoulder on the higher energy side of the carbon 1s peak indicates two distinct kinds of carbon atoms. From the width of the oxygen 1s and nitrogen 1s peaks there are at least two kinds of oxygen and nitrogen atoms present.

which has already proved valuable in a number of disparate fields¹⁵⁻¹⁸. Its great advantage in the present context is that only a very thin surface layer—estimated to be approximately 10 to 15 nm—contributes to the spectra. The method entails direct measurement of the binding energies of electrons in the 1s levels of carbon, oxygen and nitrogen. It has already been demonstrated by Siegbahn¹⁵ and others¹⁶⁻¹⁹ that shifts in energies of the core electrons are sensitive to the chemical environment of the atoms.

The electron spectra were excited by characteristic aluminium K α radiation (1487 eV) and measured with the AEI Scientific Apparatus Ltd ES 100 spectrometer. The binding energies, E_b , have not been corrected for the work function of the spectrometer nor for charging effects wrought by the ionizing radiation. Five types of polyacrylonitrile-based fibres were examined: (a) oxidized Courteille, (b) Type II, a Courteille fibre baked at approximately 1,300 K in nitrogen; (c) the same type II but oxidized to improve the bonding of the surface to a matrix, (d) type I, a Courteille fibre baked at approximately 2,400 K in argon and (e) the same type I, but oxidized.

The relevant results are shown in Figs. 1-3. Several features need comment. In the first place, the technique clearly reveals the appreciable increase in oxygen bound to the surface after oxidation. From absolute counts

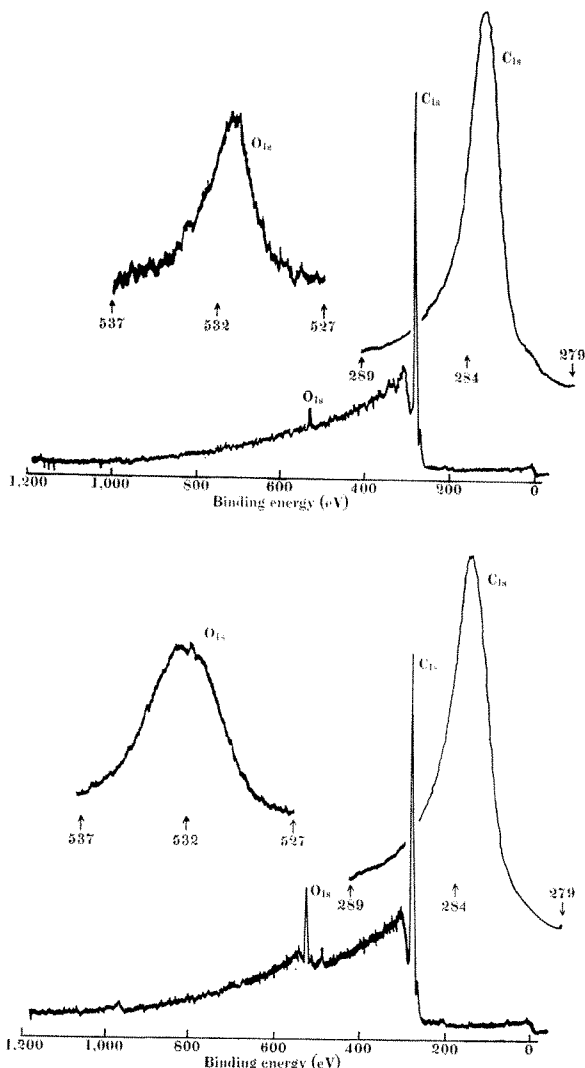

Fig. 3. High energy photoelectron spectra of nitrogen 1s, oxygen 1s and carbon 1s electrons in Courteille carbon fibre, baked at approximately 2400 K in argon (type d or type I)—top spectra; and spectra of the same fibre subjected to oxidation (type e)—bottom spectra.

recorded in other systems (unpublished work), it is estimated that there are five oxygen atoms per 100 carbon atoms in type (e). Second, from the expected half-width of the oxygen peaks (1.8 eV), it is certain that there are at least two kinds of oxygen in all of the oxidized fibres. By the same token, there are two distinct kinds of carbon atoms in sample (a). From the known shifts which have been observed by Siegbahn¹⁵, and ourselves (ref. 17 and unpublished work), the shoulder on the higher binding-energy side of the carbon 1s peak in Fig. 1 cannot be assigned to simple aliphatic carbonyls, aldehydes, carboxyl or amide groups, because the observed shift is too small. An aliphatic ether linkage may likewise be discounted because the shift is too large. (Further work, now in progress, on model aromatic compounds, will clarify the situation.) It should be noted that the profile of carbon 1s peaks in the heat-treated samples (b to e) bear no resemblance to the corresponding peak in diamond or to the carbon 1s peak in other materials, such as linear saturated hydrocarbons, where the bonding involves sp^3 hybridization. Moreover, the profile is closely similar to that obtained for graphite and vitreous carbon, which supports the suggestion⁶ that the structure of isotropic non-graphitizable carbons (vitreous or glassy carbons) might be interpreted in terms of a ribbon model, with suitable allowance for branching.

Another noteworthy feature is that almost all nitrogen atoms are driven off from the carbon surfaces by heating to 2,300 K. Spectra at high sensitivity recorded with the ES 100 spectrometer have revealed that fibres of type (b) nevertheless contain at least two kinds of nitrogen atoms, the total percentage of which, within the penetration depth, amounts to about 1 per cent.

It is clear that by utilizing higher sensitivity and if feasible, higher resolution, along with appropriate unfolding techniques, it should prove possible to identify precisely the nature of the surface bonding and to clarify the chemical structure of carbon fibres.

BIOLOGICAL SCIENCES

Brain Fatty Acid Elongation and Multiple Sclerosis

ELONGATED fatty acids in the brain are of interest because they are thought to contribute to membrane stability and cohesiveness^{1,2}. Using a technique similar to that described by Aeberhard and Menkes³, the developmental pattern of fatty acid elongation was assessed in the rat brain⁴.

Mitochondria were isolated by discontinuous sucrose gradient centrifugation from rat brains 5, 10, 15 and 20 days of age and in adulthood. Duplicate samples of 1 mg mitochondrial protein from each age group were incubated for 20 min under nitrogen in a buffered medium NADPH, NADH, ATP, and acetyl- $1-^{14}C$ -CoA. Fatty acids were extracted, transmethylated, purified, and analysed by gas-liquid chromatography. Stream-splitting allowed capillary collection of eighteen fractions for radioactive counting of individual fatty acids. Fatty acids were definitely identified by combined gas-liquid chromatography with mass spectroscopy.

The results show that fatty acid elongation reaches its maximum rate during myelination. Interestingly, the pattern of fatty acid elongation changes with brain growth and development. In younger brains, the mitochondria synthesize primarily the longer chain fatty acids, particularly $C_{22:4}$ (39.3 per cent), while the older brains form primarily the shorter chain fatty acids, particularly $C_{18:0}$ (17.7 per cent) and $C_{20:1}$ (15.3 per cent).

Of possible relevance to these findings is the report of Gerstl and colleagues⁵ that the two prominent fatty acids deficient in (frozen) multiple sclerotic brains were $C_{20:1}$ from ethanolamine glycerophosphatide and $C_{24:1}$ from cerebroside. They conclude from their data that an inadequacy of the fatty-acid elongation process and a deficit of cerebrosides represent two of the early biochemical lesions in the multiple sclerotic white matter.

Our findings, however, of a distinctive developmental prominence of $C_{20:1}$ and $C_{22:4}$ would support the view that changes in early human brain growth and development, specifically the synthesis of $C_{20:1}$, influence the eventual predisposition and development of multiple sclerosis⁶. Suggested areas of fruitful research are the control mechanisms that regulate the synthesis of elongated fatty acids and the role these fatty acids (or their elongation products) play in membrane stability, as in model membrane systems.

Localization of Encephalitogenic Basic Protein in the Intraperiod Line of Lamellar Myelin

IN the course of investigations on the immunogenic hypothesis of multiple sclerosis we have attempted the preparation of a "chemically pure myelin" and come to the conclusion that the giant molecular complex which composes the structure which the morphologist identifies as myelin has a certain integral molecular component which displays such a differentially high order of instability that this may be of great biological significance. A specific protein material is released rapidly *post mortem* from the intraperiod line of myelin and also from ultracentrifugally purified myelin *in vitro*, in conditions which make enzyme mediation improbable, and the myelin so obtained has a characteristic structure which we term "collapsed myelin". Little else besides this protein seems to be released; and this protein has been shown to be a single entity identical with the "basic encephalitogenic protein" of central nervous tissue¹⁻³.

The myelin was prepared from bovine cerebral white matter by an ultracentrifugation method modified from that of Autilio *et al.*⁴. The equilibrium density centrifugal distribution of water-washed, crude myelin product in preformed continuous sucrose density gradients varied according to the time that elapsed after the death of the animal before the excised white matter was thoroughly chilled to 4° C (K. M. J., J. P. D., S. R. A. and C. E. L., to be published). If this interval was no more than 20 min, the pattern was of a single thick band centred

Fig. 1. *a*, Density gradient showing single band of myelin from bovine brain almost instantly chilled *post mortem*. *b*, The same showing four (the two uppermost very faint) bands of myelin from bovine brain collected in chilled conditions 50-60 min *post mortem*.

at density 1.084 g cm⁻³ (Fig. 1*a*) and this product was a well preserved myelin of normal electron microscopic morphology with a repeating lamellar period of 110-120 Å (Fig. 2*a*). As the length of time *post mortem* to chilling was extended up to about 2 h, further bands appeared (Fig. 1*b*), the chief of which was centred at density 1.063 g cm⁻³ and which showed, in addition to morphologically normal myelin, a collapsed lamellar structure of 100-105 Å periodicity in which the normal faint intraperiod line was replaced by a narrow line of similar electron density to the dense line (Fig. 2*b*). A possibly identical structure has in fact been depicted in the literature⁵, as an incidental observation, and Finean⁶ has related physicochemical changes of this character to dehydration in the instance of intact peripheral nerve.

The reduced flotation density associated with these collapsed myelin structures, as well as the chemical analysis data of the myelin fractions seem to correspond to the loss of predominantly proteinaceous material from the intraperiod lines, as shown in Table 1. The corresponding data on lipid analyses will be published elsewhere.

Table 1. CHARACTERISTICS OF FRACTIONS

Ultracentrifugation layer	Mean density (g cm ⁻³)	Protein content* (mean ± s.d.)
"Collapsed" myelin	1.063	23.75 ± 0.33
Intact lamellar myelin	1.084	34.38 ± 0.85

(* Expressed as weight-equivalent of bovine serum albumin per cent.)

Incubation of initially normal myelin (which has been shown to be enzyme-free) in saline-bicarbonate buffer (pH 7.4) at 37° C for periods up to 7 days resulted in no morphological or chemical changes. Incubation in lactate buffer at pH 3.5, or in 0.1 M HCl, however, caused the almost instantaneous appearance of collapsed myelin structures, and protein appeared simultaneously in the incubation medium. Electrophoresis of the latter in 15 per cent polyacrylamide gels at pH 4.0 revealed only one protein band and this was of high mobility, as a cation. Chromatography on carboxymethyl-cellulose with a mixed H⁺/Na⁺ gradient resolved all of the material absorbing at 280 nm in a single, symmetrical peak. The amino-acid compositions of the crude incubation supernatants and of the protein therefrom, after chromato-

Fig. 2. *a*, Electron micrograph ($\times 152,000$) from "single-band myelin" as in Fig. 1*a*, showing intact intraperiod line. *b*, Electron micrograph ($\times 152,000$) from the third band of the 4-band myelin of Fig. 1*b* (the upper of the two obvious bands, ignoring the two topmost very faint bands).

graphy and ultrafiltration, were closely similar—except for the presence of sphingosine, ethanolamine and excess serine in the 0.1 M HCl supernatants (derived from hydrolysis of cerebroside and of ethanolamine and serine phosphatides). The supernatants and the purified protein were highly encephalitogenic in guinea-pigs at doses of 1 μ g (unpublished results of J. T. D., K. M. J., S. R. A. and C. E. L.). In all these examinations, the protein released from myelin was identical with basic encephalitogenic protein prepared from bovine cerebral white matter by standard defatting and acid extraction procedures for this purpose.

Analysis has shown that the released protein has the amino-acid composition: Asp₁₂, Thr₈, Ser₁₇, Glu₁₄, Pro₁₃, Gly₂₃, Ala₁₅, Val₅, Met₂, Ile₄, Leu₁₀, Tyr₄, Phe₇, (NH₂)₉, Lys₁₆, His₉, Trp₁, Arg₁₅; and a molecular weight of about 19,200 on the basis of the amino-acid analyses. The molecular weight, the tyrosine and tryptophan contents, and the ultraviolet absorption data⁷ are consistent with one another. The protein is therefore similar to that prepared from bovine spinal cord by Eylar *et al.*⁸ and by Hashim and Eylar⁹.

These observations do not, of course, imply restriction of the basic protein to the intraperiod line of the lamellar myelin (although such restriction seems probable on other grounds) but they indicate that the only protein present at this site is the basic protein. It may be significant that parallel studies in our tissue culture laboratory (C. E. L. and M. Jennings, to be published) suggest that demyelinating anti-basic-protein antibody reacts much more rapidly than other anti-brain antibodies in these cultures. The ease with which encephalitogenic protein may be released from the myelin lamellar intraperiod lines (and, *ipso facto*, into the extracellular space of nervous tissue) warrants serious consideration in the discussion of the pathogenesis of spontaneous autoimmune demyelinating disease, and we hope to delineate

the minimum deviations from physiological conditions required to release basic protein from myelin *in vitro*.

This work was sustained by grants from the Multiple Sclerosis Society of Great Britain, and, additionally, by Hull Branch of the Multiple Sclerosis Society. J. P. D. is a Multiple Sclerosis Society research fellow and K. M. J. an Eleanor Brooke Memorial research fellow.

Asparaginyl-tRNA and Resistance of Murine Leukaemias to L-Asparaginase

INTEREST in the enzyme L-asparaginase has been stimulated by the observation that it inhibits the growth of experimental and human tumours¹⁻³. Tumours sensitive to L-asparaginase require exogenous L-asparagine whereas tumours not sensitive synthesize L-asparagine from L-aspartic acid and L-glutamine. Moreover, if L-asparaginase-sensitive tumours are made resistant using suboptimal doses of the enzyme, the resistant variant possesses L-asparagine synthetase and no longer requires exogenous L-asparagine for growth^{3,4}. The critical questions now concern the regulation of L-asparagine synthetase activity.

The control of amino-acid biosynthesis seems to involve specific aminoacyl-tRNAs by direct interaction of the aminoacyl-tRNAs with a biosynthetic enzyme⁵ or by acting as repressor or co-repressor of the operon for enzymes involved in biosynthesis of the amino-acid⁶⁻⁹. Thus the amount of the L-asparagine biosynthetic enzyme, L-asparagine synthetase, may be regulated by the total amount of asparaginyl-tRNA or by the presence of a new species of asparaginyl-tRNA which acts as a repressor or a direct inhibitor. We describe here the asparaginyl-tRNA found in a leukaemia (L5178Y) lacking L-asparagine synthetase activity ("repressed") and sensitive to L-asparaginase, and in a leukaemia (L1210) possessing high L-asparagine synthetase ("derepressed") and therefore resistant to L-asparaginase³.

Murine leukaemia L1210 and L5178Y were carried in CD₂F₁ mice and were transplanted into mice of the same strains by inoculation of a dilution of the ascitic fluid. Mice were killed; the ascitic fluid was removed and centrifuged; and the cells obtained were frozen at -170°C before use.

Transfer RNA was isolated after deproteinization with phenol¹⁰, followed by chloroform extraction. The tRNA of the aqueous phase was precipitated with ethanol after each deproteinization. The precipitate was extracted with 1 M NaCl, and the supernatant containing tRNA was precipitated with ethanol. The precipitate was dissolved

in 0.1 M Tris-HCl buffer (pH 9.2) and deacylated. The sample was then neutralized and treated with deoxyribonuclease (Worthington, electrophoretically pure). Deoxyribonuclease was removed by phenol extraction and the tRNA precipitated, dried, and stored in a liquid nitrogen refrigerator at -170°C until use.

To prepare asparaginyl-tRNA synthetase, cells were homogenized in one volume of 0.1 M Tris-HCl buffer (pH 7.3) and centrifuged at $100,000g$ for 1 h. The supernatant of this step was used for the source of enzyme after addition of dithiothreitol and glycerol to final concentrations of 6 mM and 50 per cent, respectively. The samples were stored at -30°C until use. Protein was determined by the method of Lowry *et al.*¹¹.

The kinetics of asparaginyl-tRNA synthesis were determined in 0.1 ml. reaction mixtures containing 0.05 M KCl, 0.02 M magnesium acetate, 0.005 M ATP, 0.005 M CTP, 0.1 M Tris-HCl (pH 7.6), 0.001 M β -mercaptoethanol, 6.2×10^{-5} M L^{14}C -asparagine (specific activity 207 mCi/mmol, Amersham/Searle), 3×10^{-5} M each of the remaining unlabelled amino-acids except glutamine, glutamic acid and aspartic acid, 1.6 A_{260} units of tRNA and 8.0 μg of protein. L^3H -asparagine and L^{14}C -asparagine were purified by Dowex-1 ion exchange chromatography. Incubations were performed at 37°C and terminated with cold 10 per cent trichloroacetic acid (TCA). Precipitates were collected on 'Millipore' filters, dried, and the radioactivity was counted.

Acylation of tRNA before column chromatography was accomplished by increasing the reaction mixtures to 1.0 ml. and the tRNA and enzyme were proportionately increased. The tRNA was determined to be limiting by preliminary acylation studies in which concentrations of tRNA and enzyme were varied. Incubations were for 15 min at 37°C and terminated by phenol extraction. ^{14}C and ^3H -Asn-tRNA were separated from their respective labelled amino-acids by 'Sephadex G-25' chromatography. The Asn-tRNA was lyophilized, taken up in buffer, and applied to a 'Freon' column¹² for fractionation of isoaccepting species. Details of tRNA purification and acylation are described elsewhere (ref. 13 and unpublished work of R. C. G. and S. Pestka.) Conditions for conducting the 'Freon' column co-chromatography are described in the legend.

The total tRNA from these leukaemic cells varied from 6 to 25 A_{260} units/g of cells. There was no difference in the amount of tRNA obtained from L1210 and L5178Y cells. The amount of tRNA^{Asn} in L1210 and L5178Y cells was evaluated by comparing the amount of Asn-tRNA synthesized from $\text{tRNA}_{\text{L1210}}$ and $\text{tRNA}_{\text{L5178Y}}$ with L1210, L5178Y, and normal mouse liver (CD_2F_1) aminoacyl-tRNA synthetases. There was no difference in the rate or total amount of Asn-tRNA formed with any of the enzyme preparations when the same tRNA was used as amino-acid acceptor. The total Asn-tRNA synthesized was, however, approximately two-fold greater with $\text{tRNA}_{\text{L5178Y}}$ (19 pmoles/ A_{260} of tRNA) than with $\text{tRNA}_{\text{L1210}}$ (8 pmoles/ A_{260} of tRNA) with either L1210 or L5178Y aminoacyl-tRNA synthetase.

Fractionations of Asn-tRNA from L1210 and L5178Y by 'Freon' column co-chromatography are shown in Fig. 1. Three peaks of Asn-tRNA (isoaccepting species) were found with L1210 cells: a principal peak 1, an inter-

Fig. 1. Co-chromatography of ^3H -Asn-tRNA (90,581 d.p.m.) synthesized from L5178Y tRNA and L5178Y asparaginyl-tRNA synthetase and ^{14}C -Asn-tRNA (44,476 d.p.m.) synthesized from L1210 tRNA and L1210 asparaginyl-tRNA synthetase on a 'Freon' reverse phase partition column. The buffer was 0.01 M sodium acetate buffer (pH 4.5) containing 0.01 M MgCl_2 , 0.001 M EDTA, and a linear gradient of NaCl (0.30–0.65 M). The column was 1 cm \times 240 cm. Chromatography was performed at 20°C with a flow rate of 1.5 ml./min. Fractions (10 ml.) were collected and the Asn-tRNA was precipitated with 1.25 ml. of ice-cold 100 per cent TCA after the addition of 4 A_{260} units of carrier calf thymus DNA. The precipitates were collected on 'Millipore' filters, washed with 5 per cent TCA, dried by an infrared lamp, and counted in a liquid scintillation counter. Two hundred samples were collected and analysed, but only results for those containing the significant portion of the tRNA elution profile were plotted. The curves were normalized by determining the total ^3H and ^{14}C eluted from the column and expressing the ^3H and ^{14}C radioactivity of each tube as a per cent of the total ^3H and ^{14}C radioactivity respectively. These normalized values were plotted.

mediate peak 2, and a small peak 3. This pattern is identical to the Asn-tRNA profiles of normal human and mouse tissues which contain relatively high levels of asparagine synthetase ('derepressed') (our unpublished work). The Asn-tRNA profile of L5178Y differs, however, from L1210 (Fig. 1) and from normal mouse organs or human cells. Peak 1 is relatively less than peak 1 of L1210; peaks 2 and 3 are relatively greater; and an additional minor unique species (peak 4) was also fractionated. These findings were reproduced with the labelled amino-acids reversed.

To determine whether the differences obtained for Asn-tRNA with L5178Y were attributable to RNA itself or the asparagine-activating enzyme (asparaginyl-tRNA synthetase), L5178Y tRNA was acylated with asparagine-activating enzyme from L1210 and L1210 tRNA with enzyme obtained from L5178Y cells. The profiles were identical to those shown in Fig. 1, in which the autologous enzymes were used; the smaller peak 1, larger peaks 2 and 3, and peak 4 were found with L5178Y tRNA acylated with the L1210 enzyme. Thus the pattern obtained was not dependent on the asparagine activating enzyme, but was attributable to the tRNA itself.

The possibilities that peak 4 resulted from a partial degradation of a species of $\text{tRNA}_{\text{L5178Y}}$ during the isolation procedure, from a tRNA aggregate, or from a contaminating nuclease were ruled out by various experiments¹⁴. Furthermore, after isolation and deacylation of peak 4 the resulting product was shown to have an R_f identical to that of L-asparagine on paper chromatography in two solvent systems. The reproducibility of the differences in Asn-tRNA profiles between L1210 and L5178Y was tested by repeating tRNA isolation, acylation, and co-chromatography at three separate intervals on three different groups of animals. In each case results were identical to those presented in Fig. 1. We therefore conclude that the peaks of Asn-tRNA fractionated from these cells are isoaccepting species of tRNA^{Asn} and

differences in the peaks between cells "derepressed" and "repressed" for asparagine synthetase are true tRNA differences. The difference in tRNA profiles between L1210 and L5178Y cells is specific for L-asparagine, for a comparison of other aminoacyl-tRNA profiles has not revealed differences. These quantitative differences and in particular the presence of the unique small species of Asn-tRNA in the asparagine synthetase "repressed" cells (L5178Y) implicate Asn-tRNA in the regulation of asparagine synthetase.

We suggest that peak 4 of L5178Y may be a unique corepressor. In its absence asparagine synthetase is derepressed, resulting in resistance to the anti-leukaemic effects of L-asparaginase. Alternatively, the mechanism may be more complicated, involving differences between total Asn-tRNA levels of these cells as suggested in the control of the histidine operon by His-tRNA⁹.

Subsequent experiments are being performed to determine: (1) the Asn-tRNA profiles of other L-asparaginase sensitive and resistant tumours, (2) whether peak 4 Asn-tRNA interacts with asparagine synthetase, and (3) whether the addition of Asn-tRNA of L5178Y (particularly peak 4) will result in repression of asparagine synthetase and therefore sensitivity to therapy with L-asparaginase to derepressed leukaemic cells (L1210).

Antineoplastic Activity of Highly Purified Bacterial Glutaminases

SEVERAL lines of evidence motivated the treatment of neoplasms by glutaminase to cause glutamine deprivation. Certain tumour cells grown in tissue culture require glutamine at a level which is tenfold or greater than that of any other amino-acid^{1,2}. Glutamine participates in a wide variety of metabolic reactions in mammalian cells³. It has been suggested that one of the important functions of glutamine in the metabolism of certain tumours may be as a direct precursor of glutamic acid, which can then furnish the carbon for the partial operation of the tricarboxylic acid cycle from α -ketoglutarate to oxaloacetate⁴. Compared with other tissues, certain tumour cells seem to operate at a marginal level of glutamine availability because of slow synthesis⁵ and rapid utilization⁴. The glutamine antagonists, azaserine and 6-diazo-5-oxonorleucine (DON) have been shown to possess moderate antineoplastic activity, which may be enhanced by L-asparaginase⁶⁻⁸. Greenberg *et al.*⁹ reported that a glutaminase-asparaginase preparation with a

Fig. 1. Effect of L-glutamine and L-glutamate on incorporation of ¹⁴C-leucine into tumour cell protein. Washed Ehrlich cells (2.5×10^6 – 4.0×10^6 cells) were incubated at 37° C under O₂-CO₂ (95 : 5) in 2 ml. 'RMP1 1640' medium (Grand Island Biological Company) containing the indicated concentrations of asparagine, glutamine and glutamate. After 1 h, 0.5 μ Ci of uniformly labelled L-¹⁴C-leucine (311 mCi/mole) was added, and incubation continued for 1 h. Cells were harvested by centrifugation, washed, heated at 90° C for 15 min in 5 per cent trichloroacetic acid, collected on glass filter paper, and the radioactivity was determined with a liquid scintillation spectrometer. Maximal incorporation is the amount of radioactivity incorporated in a complete system containing 2.5 mM glutamine, 0.38 mM asparagine, and no glutamate. Glutamine was not added to incubation mixtures used for studying the effect of glutamate. —, With asparagine (0.38 mM); ---, without asparagine.

relatively high glutamine K_m (7×10^{-3} M) decreased the initial rate of growth of a number of tumours, including an Ehrlich ascites carcinoma, but caused no significant increase in the survival time of tumour-bearing animals. In this study, more intensive therapy with three extensively purified glutaminase preparations with considerably lower K_m values resulted in marked inhibition of an Ehrlich ascites carcinoma and significant increases in the survival time of tumour-bearing animals.

Ehrlich ascites carcinoma from Microbiological Associates (Bethesda) was carried by intraperitoneal injection of 0.2–0.5 ml. aliquots containing one million cells in 20–25 g Webster Swiss female mice from the Simonsen Company (Gilroy, California). The mice were treated with 270 IU L-glutaminase/kg/day for 16 consecutive days starting 24 h after tumour implantation. The enzyme was usually dissolved in 0.9 per cent NaCl 2–0.01 M sodium phosphate (pH 7.3) buffer before intraperitoneal injection of 0.1–0.4 ml. aliquots.

L-Glutaminase and L-asparaginase assays were performed in Tris-HCl buffer (pH 7.5) as previously described¹⁰ except that the colour formed by nesslerization of ammonia was measured 1–3 min after addition of Nessler's reagent whenever the incubation mixture contained glutamine. The methods used to determine blood amidase levels¹¹, asparagine synthetase¹², glutamyl-transferase⁵, protein¹³ (crystalline bovine albumin standard), pH-activity profiles¹⁰, and K_m values¹⁴ are described elsewhere. The method used for measuring the extent of incorporation of ¹⁴C-leucine into cell protein was essentially that of Sobin and Kidd¹⁵ except that ¹⁴C-leucine was in contact with the cells for only 1 h following a 1 h incubation of cells in non-radioactive medium.

Glutaminase preparations G1, G2, GA:1:2 and GA:2:0 were isolated from different bacteria by the enrichment technique¹⁶, G1 from a Gram-positive coccus and the other three from Gram-negative rods. The intracellular glutaminases were solubilized by ultrasonic disruption of cells and purified extensively by techniques commonly used for proteins^{10,17}. Glutaminase GA:2:0 was purified to an essentially homogeneous state, as judged by disc electrophoresis. The purified glutaminases were stable to lyophilization or storage in solution at 5° C for at

Fig. 2. Inhibition of growth of Ehrlich ascites carcinoma by highly purified glutaminase. Animals were injected intraperitoneally with 10^6 cells, and intraperitoneal treatment with glutaminase GA : 2:0 (■) was started 24 h later. least 1 week. A more detailed description of the purification steps and physicochemical characteristics of the glutaminases will be given elsewhere.

Several animal tumours were tested for glutamine and asparagine synthesizing activity. The high speed supernatant fraction of an Ehrlich ascites carcinoma homogenate had relatively little glutamyltransferase activity (5.5 nmoles/mg protein), by contrast with similar fractions of normal mouse brain, 585; liver, 432; kidney, 175; muscle, 34; and spleen, 17. The latter five tissue levels did not change significantly following two days of glutaminase treatment of normal mice. The Ehrlich tumour had a relatively high asparagine synthetase activity (7.9 nmoles/h/mg P). In the absence of glutamine, the Ehrlich ascites tumour exhibited marked reduction in the extent of incorporation of 14 C-leucine into cell protein (Fig. 1). The glutamine concentration required for maximal leucine incorporation was much higher when asparagine was removed from the medium. Furthermore, very high concentrations of glutamate (20 mM) substituted for the glutamine requirement only when L-asparagine was also present in the culture medium. Table 1 lists properties of the different bacterial glutaminases. All four enzymes have near-optimal activity in the physiological pH range, but vary in their K_m values (ranging from 4×10^{-6} to 6.5×10^{-4} M) and plasma clearance rates ($t_{1/2}$ 0.9–2.0 h).

Table 1. PROPERTIES OF VARIOUS BACTERIAL GLUTAMINASES

Preparation	G/A*	Spec. act. (IU/mg P)	K_m (M)	pH range of > 80 per cent optimal activity	$t_{1/2}$ (h)
GA : 1:2	1:2	135 (G)	2.0×10^{-4} (G)	5.5–9.3 (G) 5.9–10 (A)	0.9
GA : 2:0	2:0	150 (G)	4.0×10^{-6} (G) 8.0×10^{-6} (A)	5.8–9.2 (G) 8.5–10 (A)	2.0

† Asparaginase activity not detectable.

Repeated injections of the purified bacterial glutaminases were tolerated well by mice at a dose of 270 IU/kg/day for 16 consecutive days, and resulted in marked inhibition of abdominal distension and weight gain from tumour growth (Fig. 2). An increase in median survival time and long survival of tumour-bearing animals was seen in the glutaminase treated groups (Table 2). Heat-inactivated GA:2:0 and *E. coli* L-asparaginase did not significantly change the survival time of tumour-bearing animals.

The glutaminase-asparaginase preparations (GA:1:2 and 2:0) showed a greater antitumour effect than the enzyme with only glutaminase activity (G1). This difference may be the result of an enhanced requirement by Ehrlich cells for glutamine in the absence of asparagine (Fig. 1). It is also possible that the G1 preparation was

not as effective as the other two because of the higher K_m for glutamine. We plan to test these hypotheses by treating tumour-bearing mice with the pure glutaminases, G1 (higher K_m) and G2 (lower K_m) alone, and in combination with *E. coli* asparaginase. The GA:1:2 enzyme seemed to produce an antitumour effect at least as good as the GA:2:0 preparation, in spite of a higher K_m for glutamine and shorter plasma half-time. Further experiments are planned in order better to define the relationship between the physicochemical properties of the enzymes and antitumour activity.

When the tumour recurred in the animals treated with the GA preparations, it usually appeared after treatment was discontinued as a very slow growing subcutaneous tumour at a site of injection. An Ehrlich ascites tumour which recurred after treatment with glutaminase GA:2:0 (RAG-1), responded as well as the parent tumour to GA:2:0 treatment, in spite of an increase of glutamyltransferase activity from 5.5 to 16.9 nmoles/min/mg protein. Using glutaminase therapy with other neoplasms and other recurring Ehrlich tumours, we hope to establish the spectrum of sensitivity and define what relationship, if any, exists between glutamyltransferase activity, glutamine requirements for intracellular metabolism, and sensitivity to the amidase.

Regulatory Factor for the Transcription of the Ribosomal Genes in Amphibian Oocytes

AMPHIBIAN oocytes provide very convenient material for the study of the mechanisms that control ribosomal RNA synthesis because their pattern of ribosomal RNA synthesis does not change greatly during oogenesis. During the lampbrush stage of oogenesis (stage 4) more than 97 per cent of the RNA synthesized per unit time in the oocytes is ribosomal. This happens because the genes for ribosomal RNA are specifically amplified³⁻⁵ to such an extent that the oocyte nucleus (germinal vesicle) has an rDNA content approximately 1,500 times more than the haploid amount⁴. On the other hand, in mature oocytes (stage 6) no ribosomal RNA is synthesized^{1,2}, although the extra copies of the ribosomal cistrons are still present. There must therefore be a mechanism in these cells which turns off ribosomal RNA synthesis. It should also be remembered that ribosomal RNA synthesis resumes only after the embryo has reached gastrulation^{6,7}. Furthermore, the cytoplasmic environment in the egg and in the pre-gastrula embryo is such that when nuclei from neurula endoderm cells, active in ribosomal RNA synthesis, are transplanted into enucleated eggs, they stop ribosomal RNA synthesis, although they synthesize DNA-like and soluble RNAs and are able to sustain normal development of the embryo. Ribosomal RNA synthesis in the nuclear transplanted embryos resumes only at gastrulation⁸. It has been suggested^{9,10} that this cytoplasmic control of the pattern of nuclear transcription could be mediated through a factor which specifically inhibits ribosomal RNA synthesis.

I have investigated the mechanisms responsible for the striking change in the pattern of ribosomal RNA synthesis during oogenesis, and have evidence for the presence in the mature metabolically inactive stage 6 oocytes of a protein factor with specific inhibitory effect on the transcription of the ribosomal genes.

Female *Xenopus laevis* were injected with 1 mCi of a ¹⁴C-amino-acid mixture lacking arginine and lysine 45 days after ovulation had been hormonally stimulated. After 3 days mature stage 6 oocytes were taken from the ovary and their germinal vesicles were isolated. (Details of these procedures will be published elsewhere.) The isolated germinal vesicles were homogenized at low

ionic strength (0.07 M) and the homogenate was centrifuged at a low speed and precipitated with ammonium sulphate. The fraction precipitated, which was between 35 and 45 per cent saturated and contained 53 per cent of the radioactivity incorporated into protein in the total homogenate, was redissolved in Alberts' buffer¹¹. When microinjected into stage 4 oocytes, this fraction had a strong inhibitory effect on the synthesis of all RNA species, possibly because of the presence of toxic contaminants.

The fraction was then applied to a DNA-cellulose column¹¹ prepared with *Xenopus* erythrocyte DNA enriched in ribosomal cistrons by polylysine precipitation of the A-T-rich sequences, according to Brown's technique¹².

Only a small part of the inhibitory activity in the ammonium sulphate precipitate bound to the column while the remaining activity was recovered in the eluate. Seventy-five per cent of the inhibitory activity bound to the column was eluted at 0.6 M NaCl. When injected into stage 4 oocytes this fraction inhibited RNA synthesis (measured as incorporation of ³H-uridine into trichloroacetic acid (TCA) precipitable material) by approximately 30 per cent. Hardly any specificity of inhibition of RNA species was detected when the RNA was extracted and analysed on sucrose gradients.

The 0.6 M fraction from the DNA-cellulose column was adsorbed to DEAE-'Sephadex' and stepwise eluted by increasing the ionic strength to 0.15, 0.3, 0.6 and 1.0 M KCl. When injected into stage 4 oocytes the 0.3 M fraction seemed preferentially to inhibit synthesis of ribosomal RNA. The 0.3 M fraction was then dialysed against 0.1 M KCl and rechromatographed on DEAE-'Sephadex' with a 0.1-0.3 M KCl gradient. Because it was practically impossible to assay each tube for effects on RNA synthesis, the tubes corresponding to optical density or radioactivity peaks were pooled and labelled as indicated in Fig. 1.

Each of the peaks in Fig. 1 was checked for its effect on RNA synthesis by microinjection into young stage 4 oocytes. After injection oocytes were allowed to incorporate ³H-uridine for 2 hours and then the RNA was extracted and analysed on sucrose gradients. To avoid complications due to possible effects on the processing mechanisms of the precursor molecule, only ³H-uridine incorporation into the 40S ribosomal precursor¹³ was taken as a measure of ribosomal RNA synthesis. It is, however, clear from Fig. 2 that amount of incorporation

into the 28S and 18S regions closely follows that into the 40S molecule. Of the other RNA species, only 4S RNA synthesis was followed, both because it is the only RNA species, apart from ribosomal RNA, that can be measured with reasonable accuracy in sucrose gradients and because it is known that 4S RNA synthesis is regulated independently of ribosomal RNA¹⁴. No attempt has been made to estimate incorporation into DNA-like RNAs.

Fig. 2 shows that when peak R material is injected into stage 4 oocytes, it strongly inhibits the incorporation of ³H-uridine into the 40S ribosomal precursor, while synthesis of 4S RNA is only slightly affected.

Table 1 summarizes the results obtained when the other peaks eluted from DEAE-'Sephadex' were used for injection. Peak R clearly contains a factor which specifically inhibits ribosomal RNA synthesis. I think that the 15 per cent inhibition of the 4S RNA synthesis obtained with peak R material, as well as the slight inhibitory effects of the other peaks on both 40S and 4S RNAs, are probably a consequence of unspecific damage to the cells.

Fig. 1. DEAE-'Sephadex' chromatography of a fraction of the DNA-binding proteins from stage 6 oocytes. The 0.6 M fraction from the DNA-cellulose column was adsorbed to DEAE-'Sephadex' and stepwise eluted as described in the text. The resulting 0.3 M fraction was dialysed against 0.1 M KCl, 10 mM Tris (pH 7.4), 10 mM Mg²⁺, 6 mM mercaptoethanol, 0.1 mM EDTA, applied to a second DEAE-'Sephadex' column and eluted with a linear KCl gradient (0.1-0.3 M KCl). The loading and the elution were done at 4° C at a flow rate of 3 ml/h. The peaks were arbitrarily identified in the following way: A, tubes 10-14; B, tubes 24-29; C, tubes 31-38; D, tubes 41-45; E, tubes 62-83; R, tubes 91-101.

To substantiate further the specificity of the factor in peak *R*, its binding properties were investigated. Ribosomal RNA cistrons were isolated by the techniques of Brown¹² and Birnstiel¹⁵. In the same way I obtained DNA virtually free of ribosomal cistrons, as detected by hybridization with high specific activity *Xenopus* ribosomal RNA. The purified ribosomal cistron has a density of 1.724 and when hybridized with *Xenopus* ribosomal RNA showed a saturation of 20 per cent¹⁶.

Fig. 3 shows that the material in peak *R* had a striking binding specificity for the purified ribosomal cistrons. If the DNAs were previously denatured, binding was still observed but the specificity shown in Fig. 3 was partially lost.

It has been shown that the isolated ribosomal cistrons comprise some high-G-C "spacer" in addition to the sequences coding for the 28 and 18S RNAs^{17,18}, and so experiments are in progress to establish whether or not there is a preferential binding of the factor to any one of these components of the ribosomal RNA cistrons.

The inhibitory effect of peak *R* material disappears after trypsin digestion and heat denaturation and is resistant to ribonuclease. But although the phloroglucinol reaction for RNA¹⁹ gave negative results, a few ribonucleotides could be bound to the protein. By acrylamide gel electrophoresis the material is resolved into at least three bands, all moving to the anode but only one of them radioactive. In interpreting the binding results shown in Fig. 3 it should therefore be remembered that they apply only to the radioactive component of peak *R* material.

The results of control experiments rule out the possibility that the inhibitory effect is due to inhibition of the

Fig. 2. Sedimentation profiles of radioactive RNA extracted from control (●---●) and treated (○—○) stage 4 oocytes. The control oocytes were injected with approximately 1/10 of their volume of Gurdon's saline buffer²⁴ (88 mM NaCl; 1.0 mM KCl; 0.82 mM MgSO₄; 2.4 mM NaHCO₃; 0.41 mM CaCl₂; 0.33 mM Ca(NO₃)₂; 2.0 mM Tris HCl, pH 7.6) containing ³H-uridine (0.06 μCi per oocyte). The treated oocytes were injected with the same amount of the same saline buffer containing, in addition to ³H-uridine, 1 mμg of peak *R* protein. Seventy-five oocytes were used for each gradient. After injection the oocytes were kept in Gurdon's saline buffer. At the end of the incorporation period (2 h) the oocytes were homogenized in a Dounce homogenizer. The RNA was extracted in 0.1 M acetate, pH 5.0 containing 0.5 per cent sodium dodecyl sulphate, precipitated with alcohol and layered over a 28 ml. 15–30 per cent sucrose gradient. The gradients were centrifuged for 18 h in a Spinco SW 25.1 rotor and collected. Absorbance was recorded by Gilford continuous recorder. All fractions were precipitated with TCA and counted in a liquid scintillation spectrometer (Nuclear Chicago). The radioactivity profiles of two gradients are superimposed; the first profile (●---●) was obtained with seventy-five oocytes which did not receive peak *R* material; the second profile (○—○) was obtained with seventy-five oocytes injected with 1 mμg each of peak *R* protein. Using actinomycin I established that at least 85 per cent of counts in the 4S region were a result of real synthesis and not terminal turnover.

Fig. 3. Specific binding of peak *R* protein to purified ribosomal cistrons. Purified ribosomal cistrons (A) and DNA free of ribosomal cistrons (B) were prepared as described in the text. Both DNAs were tritiated. The ¹⁴C-labelled peak *R* protein was concentrated and mixed with rDNA or r-DNA. The incubation mixture contained, per ml.: 10 μg of DNA, 10 μg of protein, 50 μmoles of KCl and 1 μmole of EDTA. After 10 min of incubation at 37° C, 0.2 ml. of the mixture was layered on a 4.5 ml., 5–30 per cent sucrose gradient. After centrifugation for 4 h at 39,000 r.p.m. in a SW 39 Spinco rotor fractions were collected after puncturing the bottom of the tube. Each fraction was then precipitated with TCA and counted.

³H-uridine phosphorylation process or to a nuclease activity specific for ribosomal RNA.

When the extraction and fractionation procedures were repeated with germinal vesicles isolated from stage 4 oocytes active in RNA synthesis, the DEAE-'Sephadex' elution profile was different (my unpublished results) but no peak showed an inhibitory activity higher than 10–15 per cent.

The data discussed here seem to indicate that peak *R* contains a protein factor with regulatory properties specific for the transcription of the ribosomal cistrons. No conclusions, however, can be drawn about the mechanisms involved, but there are at least three possibilities: (1) the factor is a molecule with characteristics similar to a bacterial repressor^{20–22}; (2) the factor binds in some way to the RNA polymerase, thus rendering the enzyme inactive, or (3) the substance has the properties of an RNA polymerase subunit, synthesized during stage 6, incapable of initiating transcription of the ribosomal cistrons and recovered as an independent entity as a result of isolation and fractionation. There is evidence²³ that at least in stage 4 oocytes the rate of ribosomal RNA synthesis is controlled by the amount of RNA polymerase available. It should also be remembered that because of the unique features of oocytes, these cells could have special mechanisms which are not usually responsible for regulating ribosomal RNA synthesis in somatic cells.

Experiments are now in progress to test the effects of the factor on the *in vitro* transcription of the ribosomal RNA cistrons.

Table 1. EFFECTS OF DEAE-'SEPHADEX' PEAKS ON RNA SYNTHESIS

	40S RNA		4S RNA

Peak E	5,289	14.9	3,271	17.2
Peak F	1,390	71.7	3,435	13.1

The tubes corresponding to the peaks indicated in Fig. 1 were pooled and their protein concentration was determined by Lowry's method. The fractions were then diluted to the same protein concentration and injected as described in the legend of Fig. 2. Oocytes were allowed to incorporate ³H-uridine for 2 h, and RNA was extracted and analysed on sucrose gradients. The radioactivity incorporated into the 40S and the 4S regions was precipitated with TCA and measured in a liquid scintillation spectrometer (Nuclear Chicago).

I thank Dr A. Monroy for his interest and advice, Drs M. Birnstiel, G. Giudice, E. Scarano, G. P. Tocchini-Valentini and E. Weinberg for critical suggestions, and Dr D. D. Brown for details of his technique for purifying ribosomal cistrons which he supplied before publication. Some of the preliminary experiments described in this paper were done in collaboration with Dr P. Trevisano.

I also thank Mimmo Cascino for assistance.

they found that the F_1 hybrid animals derived from the mating of responder and non-responder parents gave an intermediate antibody response^{4,6}. This finding prompted us to compare the immune responsiveness of strain 2 "responder" guinea-pigs and F_1 (2×13) hybrid guinea-pigs to a DNP conjugate of a synthetic antigen (GL) controlled by the PLL gene.

F_1 hybrid guinea-pigs were produced by mating strain 2 and strain 13 guinea-pigs obtained from the National Institutes of Health Animal Production Section. Strain 2 and F_1 animals of identical sex and comparable age were immunized with 0.4 ml. of an emulsion composed of equal parts of DNP₃₃-GL in 0.15 M NaCl and complete Freund's adjuvant (Difco) which was distributed into four foot pads. Animals were immunized with either 0.01 mg or 0.1 mg of DNP₃₃-GL.

Thirteen days after immunization the guinea-pigs were skin tested with 0.01 mg of DNP₃₃-GL contained in 0.1 ml. of 0.15 M NaCl. Although there was some variation in the magnitude of the delayed response, there were no consistent differences between strain 2 and F_1 guinea-pigs (Table 1).

Table 1. DELAYED HYPERSENSITIVITY REACTIONS IN STRAIN 2 AND F_1 GUINEA-PIGS IMMUNIZED WITH DNP-GL

Strain	No. of animals	Immunizing dose of DNP-GL	Delayed hypersensitivity skin test with 0.01 mg DNP-GL at 14 days
2	4	0.01 mg	26.2* (20-35)
F_1	4	0.01 mg	19.8 (15-25)
2	3	0.1 mg	16.2 (10-20)
F_1	4	0.1 mg	26.3 (25-30)

* Average diameter in mm and range are given in parentheses.

Table 2. SERUM CONCENTRATION OF ANTI-DNP ANTIBODIES IN STRAIN 2 AND F_1 GUINEA-PIGS IMMUNIZED WITH DNP-GL, MEASURED BY PRECIPITIN ANALYSIS WITH DNP-BOVINE FIBRINOGEN

Strain	No. of animals	Immunizing dose of DNP-GL	Anti-DNP antibodies after 14 days (mg/ml.)	28 days (mg/ml.)
2	4	0.01 mg	0.46* (0.23-0.66)	0.71 (0.57-0.83)
F_1	4	0.01 mg	0.45 (0.37-0.52)	0.73 (0.51-1.05)
2	3	0.1 mg	0.88 (0.83-0.96)	1.8 (1.56-2.13)
F_1	4	0.1 mg	1.3 (0.95-1.47)	1.42 (0.83-2.3)

* Mean value and range are given in parentheses.

Guinea-pigs were bled 14 and 28 days after immunization. Anti-DNP antibodies were measured by quantitative precipitation with DNP₁₄₃-bovine fibrinogen as described by Eisen *et al.*⁷. Table 2 shows that the amount of antibody produced by F_1 and strain 2 animals is similar.

Table 3. ASSAY OF SERUM ANTI-DNP ANTIBODY LEVELS BY A MODIFICATION OF THE FARR TECHNIQUE IN STRAIN 2 AND F_1 GUINEA-PIGS IMMUNIZED WITH DNP-GL

Strain	No. of animals	Immunizing dose of DNP-GL (mg)	Per cent binding of ³ H-DNP-EACA by globulin fraction after 14 days*	28 days†
2	4	0.01	54.5‡ (34.2-65.5)	51.4 (34.2-65.5)
F_1	4	0.01	49.9 (47.7-54.6)	58.4 (45.6-63.7)
2	3	0.1	49.6 (39.3-63.3)	55.2 (37.8-65.7)
F_1	4	0.1	55.9 (48.8-63.9)	58.4 (38.5-72.5)

* Percentage binding of 0.1 ml. of 10^{-8} M ³H-DNP-EACA by globulin fraction of a 1/10 dilution of 0.1 ml. serum.

† Percentage binding of 0.1 ml. of 10^{-8} M ³H-DNP-EACA by globulin fraction of a 1/100 dilution of 0.1 ml. serum.

‡ Mean value and range are given in parenthesis.

Effect of Gene Dose on the Immune Response to a 2,4-Dinitrophenyl Glutamic Acid Lysine Copolymer

DOMINANT autosomal genes controlling specific immune responses to simple synthetic polypeptides of known composition have been described. In the guinea-pig, the immune response to poly-L-lysine (PLL), a copolymer of glutamine and lysine (GL), polyarginine, protamine and haptenic derivatives of these materials is controlled by the presence of the autosomal dominant, "PLL gene". As well as random bred Hartley guinea-pigs, in which the gene is variably present, there are inbred strains in which the gene is always present (strain 2) or always absent (strain 13). Strain 2 and Hartley guinea-pigs with the PLL gene are termed "responders" while strain 13 and the rest of the Hartley guinea-pigs are termed "non-responders". The (2×13) F_1 hybrid animal is heterozygous for the PLL gene and is always phenotypically a responder animal¹⁻³.

McDevitt and his associates have demonstrated that the immune response of inbred strains of mice to a related series of three multibranching polypeptide antigens is also controlled by an autosomal dominant gene (with multiple alleles), termed the "Ir-1 locus"^{4,5}. While investigating the immune response in these inbred mice,

Anti-DNP antibodies were also measured by a modification of the Farr technique in which the binding of ³H-DNP-EACA by the globulin fraction of the antisera was measured⁸. The data in Table 3 demonstrate no difference between F_1 and strain 2 guinea-pigs as detected by percentage binding of ³H-DNP-EACA by their sera. The fact that a ten-fold greater dilution of the 28 day sera gave approximately the same binding as the 14 day sera without a marked change in the amount of antibody present, is a consequence of the increase in binding affinity of the antibody with time after immunization. Because the F_1 and strain 2 sera behaved identically in this respect, it seems that F_1 and strain 2 animals produce antibodies of equivalent affinity for the DNP ligand.

Previous studies of these two immune systems have revealed many similarities³. The PLL gene in the guinea-pig and the Ir-1 gene in the mouse are both autosomal dominant traits controlling specific immune responses. In both systems it is possible to transfer the ability to respond from F₁ responder animals into lethally irradiated, non-responder parental recipients by the transfer of immunocompetent cells^{9,10}.

McDevitt and Chinitz have shown by breeding studies that the Ir-1 locus is closely associated with the major mouse histocompatibility locus (H-2) in the IX mouse linkage group⁵. We have investigated whether the PLL gene is linked to the major histocompatibility locus of the strain 2 responder animal. By back-crossing the heterozygous F₁ animal with the non-responder strain 13 animal, offspring were obtained which could be tested for both the presence of the PLL gene and the presence of the strain 2 histocompatibility antigen. The presence or absence of the PLL gene was always correlated with the presence or absence of the strain 2 major histocompatibility antigen¹¹. Thus both Ir-1 and PLL loci appear to be linked to the major histocompatibility locus in their respective species.

Our results demonstrate the first difference detected between the two systems. The F₁ hybrid mouse possessing the Ir-1 gene produces an antibody response intermediate between non-responder and responder parents. The F₁ hybrid guinea-pig possessing only a single PLL gene seems to have an immune response equivalent to its responder (strain 2) parent. Thus a gene dose effect is operative for the "Ir-1 gene" in mice which is not present for the PLL gene in guinea-pigs. Although the significance of this difference is not understood, analysis of gene dose effects in genetically controlled immune systems may provide insight into the mode of action of immune response genes.

Vascular Hyper-reactivity with Sodium Loading and with Deoxycorticosterone Induced Hypertension in the Rat

HYPERTENSION may be induced in several species by excessive dietary salt, and is accentuated by the removal of a kidney and deoxycorticosterone administration¹⁻⁵. The blood pressure is raised because peripheral resistance is increased, but the exact mechanism leading to arteriolar narrowing is unknown. Vascular hyper-reactivity to pressor stimuli has been implicated^{6,7}, but when assessing this it is difficult to determine the relative importance

of true vascular smooth muscle hyper-reactivity, smooth muscle hypertrophy and minor changes in starting diameter of the resistance vessels^{8,9}. These problems can be largely circumvented by studying vascular reactivity in isolated perfused organs devoid of their normal nervous and humoral stimuli, and for this purpose we developed the vascular bed of the isolated perfused rat tail¹⁰. This preparation has a relatively simple structure; it includes terminal resistance vessels, and when perfused at constant flow rates with an artificial electrolyte medium containing dialysed bovine serum albumen, baseline resistance is stable for several hours. The tail responds with reproducible dose response curves to a variety of pressor agents.

Three groups of seven male Wistar rats were studied. Animals in one group were left intact and received a normal diet and tap water. Rats in the two remaining groups had one kidney removed and were given 1 per cent NaCl and 0.2 per cent KCl to drink. After two months, 12.5 mg deoxycorticosterone was given intramuscularly twice weekly to one of the nephrectomized groups. Systolic blood pressures were recorded in conscious warmed animals by tail plethysmography using a silicon strain gauge transducer. Pressure increased in the animals receiving deoxycorticosterone.

Perfusion studies were carried out 4 months after the original nephrectomy. By this time the nephrectomy/saline/deoxycorticosterone animals had been hypertensive for 4 weeks, and the day before tail perfusion studies, pressures were 177.9 (\pm s.d. 5.7) in this group compared with 120 (\pm s.d. 5.8) in the nephrectomy/saline animals ($P < 0.001$ for differences between means using Student's *t* test).

Animals were prepared for constant flow isolated tail perfusion¹⁰. Rats from the nephrectomy saline group were studied alternatively with those from the nephrectomy/saline/deoxycorticosterone group and before the untreated group. In each experiment two dose response curves to noradrenaline were obtained using bolus injections over a dose range 3–800 ng. The increase in resistance in response to noradrenaline was expressed as the change in pressure in mm Hg in the perfusion circuit proximal to the tail artery. Values from the two dose response curves to noradrenaline in each perfusion were averaged and these averages used subsequently.

The hypertensive deoxycorticosterone/saline/nephrectomy animals showed increased reactivity to noradrenaline at all doses (Fig. 1). Responses of the saline/nephrectomy group were intermediate to those of the hypertensive and intact animals. The differences were large, the average doses required to give a pressure increment of 50 mm Hg in tails from the three groups were 11, 66 and 170 ng in decreasing order of sensitivity. Wilcoxon's rank test was used to test the differences between groups as regards the doses required to give a 50 mm Hg pressure increment and was significant at $P < 0.01$ in each instance.

Responses to a single dose of 200 ng of synthetic angiotensin II amide ('hypertensin', Ciba) were recorded in the saline/nephrectomy and deoxycorticosterone/saline/nephrectomy groups only, and gave mean pressure increments of 11.7 (\pm s.d. 3.4) and 15.9 (\pm s.d. 9.1) respectively. This difference was not statistically significant ($P > 0.1$). Full dose response curves to angiotensin II were not obtained because of prolonged tachyphylaxis. Baseline resistance was not increased in preparations from the hypertensive rats and was slightly higher in the intact rats compared with the saline/nephrectomy group (Table 1). The intact group were also significantly heavier than the other animals at the time they were studied. As a further index of severity of blood pressure elevation heart weight was expressed as a percentage of body weight; values were greater in the deoxycorticosterone/saline/nephrectomy animals than in the other two groups (Table 1).

The increased reactivity of the hypertensive deoxy-

Fig. 1. Each curve represents the mean of two dose response curves to noradrenaline on each rat tail. The ordinate represents changes in pressure in mm Hg in the perfusion circuit in response to each dose of noradrenaline. Flow was constant at 0.5 ml/min with a bath temperature of 34° C. Increased vascular reactivity in the saline/nephrectomy rats (middle graph) and a further increase in the deoxycorticosterone/saline nephrectomy animals (lower graph) is shown.

corticosterone/saline/nephrectomy animals seemed to be specific for noradrenaline, and was not apparent when angiotensin II was injected. From the lack of significant differences in response to angiotensin we conclude that the large differences in response to noradrenaline did not result from vascular smooth muscle hypertrophy. This is further supported by the increased reactivity of the normotensive nephrectomy/saline animals compared with the untreated group. It therefore seemed likely that the increased reactivity either resulted from a change in the adrenoceptor, or from the local metabolism of noradrenaline. DeChamplain *et al.*¹¹ have shown that deoxycorticosterone and salt administration reduce noradrenaline metabolism by cardiac sympathetic nerves and they postulated that this occurred in arteries, and by accentuating the effect of autonomic nerve activity led to hypertension. This mechanism is unlikely to account for our experimental results, because although the magnitude of resistance change in response to noradrenaline increased with salt loading and deoxycorticosterone, the duration of response tended to decrease.

Table 1

	(Group 1) Untreated	(Group 2) Saline/ nephrec- tomy	(Group 3) Deoxycorti- costerone/ saline/ nephrectomy	P values comparing group means
Relative heart weight (per cent)	0.239 ±0.028 (6)	0.267 ±0.027 (7)	0.343 ±0.012 (7)	1 vs 3 <i>P</i> < 0.001 2 vs 3 <i>P</i> < 0.001
Total body weight (g)	549.4 ±41.3 (7)	426.6 ±72.98 (7)	370.0 ±34.75 (7)	1 vs 2 <i>P</i> < 0.01 1 vs 3 <i>P</i> < 0.001
Tail weight (g)	11.43 ±1.08 (7)	10.0 ±1.91 (7)	8.96 ±0.86 (7)	1 vs 3 <i>P</i> < 0.001
Baseline resistance (mm Hg)	22.57 ±3.60 (7)	17.43 ±3.95 (7)	18.71 ±2.75 (7)	1 vs 2 <i>P</i> < 0.05

Values are given as the mean ± s.d. Figures in parentheses are numbers of animals. Student's *t* test was used to compare groups. *P* values < 0.05 are shown in the right hand column.

In conclusion it has been shown that resistance vessels in the isolated perfused tail of animals treated by unilateral nephrectomy and salt loading show increased reactivity to noradrenaline and that this effect is accentuated in animals developing hypertension after administration of deoxycorticosterone. It is important to confirm that this change is specific for catecholamines and to establish whether there is a direct relationship between the altered vascular reactivity and the development of hypertension.

Salsolinol, an Alkaloid Derivative of Dopamine formed *in vitro* during Alcohol Metabolism

THE Pictet-Spengler reaction is a special example of the Mannich reaction involving condensation of β -aryl-ethylamines with carbonyl compounds¹. In the case of phenylethylamines the resulting products would be 1,2,3,4-tetrahydroisoquinolines, which are particularly interesting because they could be formed from endogenous biogenic amines. The synthesis of simple tetrahydroisoquinolines in physiological conditions which occur in plants was described in 1934². The facility of this chemical reaction between dopamine and acetaldehyde in conditions which exist in both plants³ and animals^{4,5} has been confirmed. Because acetaldehyde is the primary metabolite of ethanol, it has been suggested that tetrahydroisoquinolines are formed in mammals after the ingestion of alcohol⁴⁻⁶. Indeed, this reaction forms the basis for the histochemical localization of catecholamines in nerve tissue for which formaldehyde vapour is used as the carbonyl agent. Reaction products of this type have been demonstrated in animals after administration of methanol⁷.

Salsolinol (1-methyl-6,7-dihydroxy-1,2,3,4-tetrahydroisoquinoline) is a condensation product of the neuroamine, dopamine, with the proximal metabolite of ethanol, acetaldehyde (Fig. 1). We have examined the formation of this tetrahydroisoquinoline alkaloid in rat liver and brain-stem homogenates. Because the intermediate metabolism of dopamine, ethanol, and acetaldehyde involves nicotinamide-adenine dinucleotide (NAD)-linked alcohol dehydrogenase and NAD-linked aldehyde dehydrogenase pathways, two tissues with widely differing capacities to oxidize alcohol or acetaldehyde were selected to determine the effect of rate of formation and metabolism of acetaldehyde on the formation of salsolinol. Incubation mixtures consisted of dopamine (0.2 μ Ci of ¹⁴C-dopamine plus 3.3 mM dopamine-HCl), acetaldehyde (0.5–4 mM) or ethanol (100 mM), and 1 ml. of tissue homogenate equivalent to 100 mg of rat brain-stem or 50 mg of rat liver. The total volume was 4.0 ml. In some experiments exogenous cofactor, (4 mM) NAD, was added. Incubations were carried out in 25 ml. Erlenmeyer flasks exposed to air in a shaking water bath for 30 min at 37° C. Ethanol

Fig. 1. Representation of the mechanism of formation of salsolinol by condensation of dopamine with acetaldehyde derived from enzymatic (alcohol dehydrogenase, ADH) conversion of ethanol.

Fig. 2. Exact tracings of thin-layer chromatograms of authentic dopamine and salsolinol standards and ¹⁴C-dopamine and ¹⁴C-salsolinol isolated from rat liver homogenates. Histograms illustrate the effect of ethanol and acetaldehyde on the relative amounts of radioactive dopamine remaining and labelled salsolinol formed. Percentages and R_F values for experimental samples represent the means of fifteen determinations. R_F values for standard compounds are the means of twenty-five observations.

or acetaldehyde were added 1 min before the addition of dopamine.

Tissue homogenates were precipitated with 45 per cent perchloric acid and after removal of tissue protein and perchlorate salts, the extracts were adjusted to pH 8.4 and applied to columns of alumina (1 g of aluminium oxide, Woelm, neutral). Catechol compounds were eluted from alumina (7 ml. of 0.2 M HCl), adjusted to pH 2, and quantitatively transferred to four 100 mm columns of a strongly acidic cation exchange resin (Dowex AG-50W X 4, 100–200 mesh, H⁺ form). The catechol bases were adsorbed on this resin and completely separated from the deaminated catechols which passed through in the effluent. Two catechol bases (dopamine and salsolinol) were quantitatively eluted from the resin with 80 ml. of 0.5 M HCl. This procedure completely separates dopamine and salsolinol from the other catechol base metabolite of dopamine, tetrahydropapaveroline⁸. Dopamine and salsolinol followed almost identical elution patterns, but were readily separated and quantitated by thin-layer chromatography using cellulose Whatman 'CC 41' (Fig. 2). Chromatograms were developed in a mixture of chloroform, methanol and water (70:50:5) in the cold (4° C) for 15 cm under nitrogen, and spots were visualized by spraying with ferric chloride-potassium ferricyanide reagent. Authentic dopamine had an R_F of 0.39 and salsolinol standard an R_F of 0.68. Chromatography of the 'AG-50W' eluate in the presence of ethanol and acetaldehyde demonstrated two distinct and separate spots, identical with standard compounds (Fig. 2). The identity of ¹⁴C-salsolinol was further substantiated by gas-liquid chromatography⁹.

Table 1. EFFECT OF ETHANOL AND ACETALDEHYDE ON THE DISAPPEARANCE OF DOPAMINE AND THE FORMATION OF SALSOLINOL IN PHOSPHATE BUFFER, AND RAT BRAIN-STEM OR LIVER HOMOGENATES

Values represent μ moles \pm standard deviation.

When ethanol was mixed with dopamine in phosphate buffer no salsolinol was generated (Table 1). Thus in the experimental conditions (30 min incubation at 37° C, pH 7.4) there was no spontaneous breakdown of ethanol to acetaldehyde. Addition of varying amounts of acetaldehyde, however, resulted in the *in vitro* synthesis of this tetrahydroisoquinoline alkaloid. The formation of salsolinol was directly proportional to the concentration of acetaldehyde when the concentration of dopamine was kept constant. The percentage radioactivity converted to salsolinol was 14.2–66.7 per cent in the presence of acetaldehyde (0.5–4 mM), not significantly different from the value obtained with brain-stem (+NAD) or liver homogenates (–NAD).

When 100 mM ethanol was added to incubation mixtures containing rat brain-stem homogenates and 16 μ moles of NAD, 2 per cent of the total radioactivity was converted to salsolinol (Table 1). The synthesis of salsolinol from ethanol in brain homogenates supports the finding of an alcohol dehydrogenase in the brain¹⁰, for this condensation product could only be formed if acetaldehyde were generated in the reaction mixture. When brain-stem homogenates were incubated with 0.5–4 mM acetaldehyde dopamine decreased (from 89.6 to 27.9 per cent) and salsolinol increased (from 10.4 to 72.1 per cent). Incubation of rat liver homogenates with 100 mM ethanol in the absence of NAD also resulted in the conversion of a small percentage (6.6) of the total radioactivity to salsolinol. Salsolinol could be formed only if ethanol were metabolized to acetaldehyde in these conditions. Even in the absence of added cofactor, sufficient endogenous NAD was presumably present to allow activity of liver alcohol dehydrogenase. Salsolinol production in rat liver homogenates (10.5–74.2 per cent of ¹⁴C) in the absence of NAD was proportional to the concentration of acetaldehyde, and closely paralleled that found when rat brain-stem homogenates were used in the presence of cofactor. This effect is probably due to the limited amount of NAD-linked aldehyde dehydrogenase in brain compared with liver¹¹. In the eluate from incubation mixtures of liver homogenate in the presence of NAD and 100 mM ethanol, all radioactivity was present in dopamine. The failure to form salsolinol in the presence of ethanol and cofactor may have been due to the rapid oxidation of generated acetaldehyde. In ethanol metabolism, NAD-linked alcohol dehydrogenase is the rate limiting enzyme¹², and so NAD-linked aldehyde dehydrogenase would quickly convert acetaldehyde to acetate and prevent it from condensing with dopamine. In the presence of NAD and acetaldehyde, salsolinol synthesis was reduced by 20–40 per cent. Thus the rapid oxidation of acetaldehyde by NAD-linked aldehyde dehydrogenase inhibited the formation of salsolinol by effectively reducing one of the requisite reactants, acetaldehyde.

Substantial salsolinol formation from dopamine occurred in both rat brain-stem and liver homogenates when acetaldehyde was added in concentrations approximating those which occur *in vivo*¹³. This isoquinoline alkaloid was also found in brain-stem and liver homogenates in the presence of ethanol (Table 1). It has been suggested that tetrahydroisoquinolines are formed from catecholamines as a result of ethanol ingestion and subsequent generation of acetaldehyde^{4–6}. Cohen and Collins⁶ reported that retrograde perfusion of adrenal glands with large

amounts of acetaldehyde resulted in the formation of tetrahydroisoquinolines derived from both noradrenaline and adrenaline. These condensation products had the same *R_F* values as the products of reaction between these catecholamines and acetaldehyde *in vitro*. The amounts of acetaldehyde perfused were far in excess of concentrations found after ingestion of alcohol. Such large quantities were probably necessary because this reaction with catechol-containing compounds which have substitutions on the side chain is quite slow. Robbins⁴ found the second order rate constants (l. mole⁻¹min⁻¹) for alkaloid formation (pH 7.4, at 37° C) between acetaldehyde and dopamine, L-dopa or noradrenaline to be 15.3, 6.1, and 1.9, respectively.

Thus this reaction is retarded appreciably when the ethylamine moiety contains substituent groups. The ease with which dopamine and acetaldehyde react (Table 1) indicates that the possible endogenous formation of an alkaloid after administration of alcohol would be most likely with this biogenic amine, especially in view of the short half-life of acetaldehyde *in vivo*¹⁴.

Tetrahydroisoquinoline alkaloids of the salsolinol type have been shown to have both central and peripheral pharmacological effects^{15–17}. These alkaloids may have either central nervous system depressant or stimulant and convulsant properties^{15,17}, vasopressor or depressor actions^{16,17}, various effects on smooth muscle^{16,17}, and lipid mobilizing activity¹⁸. It is intriguing to speculate that if tetrahydroisoquinoline alkaloids were formed *in vivo*, they might explain some of the pharmacological and behavioural effects produced by either acute or chronic ingestion of alcohol.

We thank Mr J. A. Huff for technical assistance. This investigation was aided by a grant from the National Institute of Mental Health, US Public Health Service.

Proteins of Rabbit Reticulocyte Ribosomal Subunits

By comparison with those of prokaryotic cells, especially *Escherichia coli*, little is known about the ribosomes of eukaryotes. The present analysis of ribosomal proteins from rabbit reticulocytes indicates that—in spite of the larger size of the particle and a higher protein content—the number of different proteins is not significantly greater than that in *E. coli* ribosomes. There may be multiple copies of some proteins and other proteins may be present in only a fraction of the ribosomes. Proteins from both ribosomal subunits are evidently considerably more basic than the corresponding proteins from *E. coli* subunits.

The amino-acid compositions of the total protein of the two subunits are strikingly similar (Table 1) as is indeed the case in *E. coli*¹. The ratio of basic to acidic amino-acids in reticulocytes is, however, 6 compared with 1.4 in the case of *E. coli*.

The multiplicity of ribosomal proteins from reticulocytes is clearly demonstrated by electrophoresis in polyacrylamide gels in conditions which have also been applied to *E. coli* ribosomal proteins (Fig. 1)². Some thirty zones for the large subunit and twenty for the small may be discerned. Similar numbers are reported for other eukaryotic ribosomes³ and *E. coli* ribosomes.

Gel electrophoresis in sodium dodecyl sulphate provides a means of estimating the molecular weights of all the separated proteins⁴⁻⁷. Fig. 2 shows that the resolution of ribosomal proteins is comparable with that in the conventional electrophoretic system: the large subunit gives eighteen major and ten minor zones, whereas the small subunit gives thirteen major and eight minor zones.

The relationship between electrophoretic mobility and molecular weight (Fig. 3) allows the derivation of molecular

Fig. 1. Gel electrophoresis of ribosomal proteins from rabbit reticulocyte ribosomal subunits. To the ribosome solution (see Table 1) at 1–5 mg/ml. was added an equal volume of 4 M LiCl²⁴. The suspension was incubated at 0° C for 2 h and centrifuged at 600g to sediment the RNA. The supernatant was dialysed against 0.033 M sodium acetate and 6 M urea (freshly diazotized) (pH 5.6). Disc electrophoresis in 10 per cent polyacrylamide gels was performed in tubes of 6 mm internal diameter according to the method of Leboy and Flaks². The sample was composed of approximately 100 µg protein in 0.1 ml. solvent to which 0.01 ml. of a 50 per cent sucrose solution containing a trace of pyronine Y to serve as a tracking dye was added. Electrophoresis was carried out for 3 h at 5 mA/gel at room temperature in a Shandon electrophoresis tank. The gels were soaked overnight in 20 per cent sulphosalicylic acid and then stained for 2–4 h in a solution of 0.1 per cent Coomassie blue in water. The gels were electrophoretically de-stained and stored in 5 per cent acetic acid. These proteins have also been run in starch gel containing phenylacetic acid²⁴.

Fig. 2. Sodium dodecyl sulphate (SDS) electrophoresis of ribosomal proteins. The ribosomal subunits (Table 1) were made 1 per cent in SDS and dialysed overnight against a solution of 0.1 per cent SDS, 5 M urea (freshly diazotized), 0.1 M β -mercaptoethanol, and 0.01 M phosphate buffer (pH 7.6). To the sample containing 250 µg protein in 0.1 ml. was added 0.01 ml. of 0.002 per cent bromophenol blue in 50 per cent sucrose. Disc electrophoresis in 7.5 per cent polyacrylamide gels cast in tubes of 8 mm internal diameter and 20 cm length was performed as previously described⁴⁻⁷. Electrophoresis was at 5 mA/gel constant current at room temperature for 8 h with several changes of reservoir buffer using a Shandon disk electrophoresis tank. Gels were stained and de-stained as in Fig. 1.

weights for the ribosomal proteins in the range of 16,000–60,000. About half of the total number seem to have molecular weights greater than 40,000. All of the *E. coli* ribosomal proteins are smaller than 40,000 (refs. 8, 9).

Table 1. AMINO-ACID COMPOSITION OF RABBIT RETICULOCYTE RIBOSOMAL SUBUNITS

Amino-acid	Mole per cent of amino-acid	
	Large subunit	Small subunit
Aspartic acid	6.73	6.75
Threonine	3.73	4.42
Serine	5.00	4.54
Glutamic acid	8.40	9.88
Proline	4.20	3.67
Glycine	5.80	6.42
Alanine	6.92	5.88
Cysteine	7.20	8.14
Valine	5.45	5.76
Methionine	1.59	1.42
Isoleucine	4.20	4.32
Leucine	6.72	6.65
Tyrosine	2.14	2.12
Phenylalanine	2.73	2.73
Lysine	8.30	7.25
Histidine	2.02	1.89
Arginine	5.83	5.49
Ammonia	12.70	11.58

Rabbit reticulocyte ribosomes were dissociated with ethylenediaminetetraacetic acid as previously described²⁷. The fractions were concentrated by centrifugation at 105,000g for 16 h. The ribosomal pellets were redissolved in 0.025 M KCl–0.001 M MgCl₂–0.05 M Tris–10 per cent sucrose (pH 7.6) (medium A). RNA was extracted by the guanidinium chloride procedure²⁸. The ethanol supernatants containing the ribosomal proteins were dialysed extensively against water and the protein was lyophilized. Amino-acid compositions were determined with a Spinco amino-acid analyser after hydrolysis with 6 M HCl at 110° C for periods of 24, 48 and 72 h. Extrapolations for the labile residues were performed in the usual manner. The relative weights of the individual amino-acids except for cysteine and methionine agreed within 5 per cent in duplicate experiments. The relative weights of cysteine and methionine agreed within 20 per cent. Tryptophan was not determined but previous analyses indicate the amounts in the unfractionated protein is only about 1 per cent^{29,30}. This should not significantly alter the calculated relative molar composition. The mole per cent of acidic residues is calculated by adding aspartic acid and glutamic acid together and subtracting ammonia. The mole per cent of basic residues is calculated from the sum of lysine and arginine.

Fig. 3. Molecular weight calibration of SDS-polyacrylamide gels. Electrophoresis was carried out in 7.5 per cent polyacrylamide gels containing SDS as described in Fig. 2. 50 μ g samples of proteins of known molecular weight prepared as described for Fig. 2 were subjected to electrophoresis. The migration distances relative to the bromophenol blue dye are plotted against the logarithm of the molecular weight. The different symbols represent separate experiments.

The possibility that each electrophoretic zone represents a unique protein species present in every ribosome may be examined by three independent criteria:

(1) The sum of the molecular weights of the proteins leads to values of 0.66×10^6 – 1.0×10^6 for the protein of the large subunit and 0.41×10^6 – 0.8×10^6 for the protein of the small subunit (Table 1). Because the molecular weights of the RNA components of rat liver ribosomes are 1.6×10^6 and 0.6×10^6 (refs. 10, 11), respectively, the sum of RNA and total protein leads to values of 2.3×10^6 – 2.6×10^6 and 1.0×10^6 – 1.4×10^6 for the molecular weights and 29–39 and 40–58 per cent for the protein content of the subunits. The calculated maximum molecular weight of the large subunit falls well below the true molecular weight of the rat liver subunit, 3.1×10^6 , measured by equilibrium centrifugation¹¹, and the protein content is at most two-thirds of the measured value of 48 per cent. The calculated values of 1.0×10^6 – 1.4×10^6 for the molecular weight and 40–58 per cent for the protein content of the small subunit spans the measured values of 1.2×10^6 (ref. 10) and 52 per cent respectively.

(2) Because the area under the densitometer traces of the polyacrylamide gels stained with Coomassie blue should be proportional to the relative amount of protein¹², a gradation in the size of the peaks from high to low molecular weights would be expected. Fig. 4 does not bear out this expectation.

(3) The number of different proteins in the large and small subunits may be predicted by dividing the weight of protein in the subunit by the weight-average molecular weight of the unfractionated proteins of rat liver ribosomes, 26,000, measured by equilibrium centrifugation¹³. Thus the large subunit should contain fifty and the small subunit twenty different proteins.

A check on the average molecular weight of the proteins is obtained from these data in two different ways: First, assuming single copies of the proteins, values of 41,000–42,300, for the large subunit and 34,800–42,000 for the small subunit are calculated from the molecular weight distribution shown in Fig. 2. Second, making no assumptions and merely dividing the densitometer trace (Fig. 4) into halves of equal area values of 30,000 and 28,000, rather closer to the measured value 26,000 are obtained.

The observed discrepancies can only be explained if either some of electrophoretic zones are heterogeneous—unlike the case of *E. coli*—or if there are multiple copies of certain proteins in the ribosome. This situation is in striking contrast with *E. coli* where no more than one of each type of proteins is found, at least in the small subunit, and the expected number of different proteins is found in both subunits. It may be recalled that the RNA component of the large subunit of eukaryotic ribosomes is up to 60 per cent larger than that of *E. coli*¹⁴. *E. coli* ribosomal RNA seems to be derived at least in part by gene duplication^{15–18}. Additional binding sites for particular ribosomal proteins in the eukaryotic ribosomes could also have arisen in this manner.

As many as one-third of the ribosomal proteins of *E. coli* may be present in less than stoichiometric amounts in the ribosome⁹. Because the relative amounts of the proteins do not apparently vary with the growth conditions it is unlikely that the minor components are required to translate different sets of messenger RNAs. It has been proposed that they are involved instead in different stages of translation.

Reticulocyte ribosomes are concerned with the synthesis of essentially only two different proteins, the α and β -chains of haemoglobin, so that it is especially unlikely that the presence of numerous minor components reflects the requirements of specific messenger RNAs. Some of the minor components may reflect cytoplasmic contamination: this would explain the variation found between the proteins of the small subunit from different animal tissues¹⁹. Other proteins, as suggested previously, may be cyclically bound and released from the ribosome during protein synthesis.

The similarities in the mechanism of protein synthesis by *E. coli* and eukaryotic ribosomes, particularly as regards chain initiation, has been stressed in a number of recent publications^{20,21}. At least one important point

Fig. 4. Electrophoretic patterns of ribosomal proteins in polyacrylamide gels containing SDS. Densitometry of the polyacrylamide gels shown in Fig. 2 was performed using a Joyce-Loebel 'Chromoscan'. The scans were traced on heavy cardboard and cut at the position of the arrow into equal halves. This position indicates the average molecular weight by reference to Fig. 2 (Table 2).

Table 2. COMPARISON OF CALCULATED AND OBSERVED COMPOSITIONS OF RIBOSOMAL SUBUNITS

Subunit	Molecular weight of total protein			Percentage of protein by weight			Molecular weights of subunits			Weight average molecular weights of proteins			Number of proteins		
	Calculated*	Min- imum	Maxi- mum	Calculated†	Min- imum	Maxi- mum	Calculated‡	Min- imum	Maxi- mum	Calculated**	Min- imum	Maxi- mum	Calculated††	Min- imum	Maxi- mum
Large	655,900	1,038,900	1,500,000	29.0	39.4	48	2,255,000	2,638,900	3,100,000	41,000	42,300	30,000	50	18	28
Small	408,600	810,000	570,000	40.0	58.0	52	1,008,600	1,410,000	1,200,000	34,900	42,000	28,000	20	13	21

* Sum of the molecular weights listed in Fig. 2. The minimum value includes only the "major" zones. The maximum value includes the "minor" zones.

† Product of the observed fraction of protein by weight times the observed molecular weight of the subunit.

‡ Sum of the calculated molecular weights divided by the sum of the calculated molecular weights plus the observed molecular weight of the RNA component^{9,10}. Minimum value includes only the "major" zones of Fig. 2. Maximum value includes the "minor" zones.

§ RNA was estimated from the spectrum³¹ and protein by the Lowry procedure using bovine serum albumin as a standard (ref. 32 and unpublished results of H. J. G. and H. W. S. King). The validity of bovine serum albumin as a protein standard has been established for Jensen sarcoma ribosomes by comparison with the dry weight determination³².

|| Sum of the calculated molecular weight of protein and the observed molecular weight of RNA^{9,10}. The minimum value includes only the "major" zones, and the maximum value includes both the "major" and "minor" zones of Fig. 2.

¶ Molecular weights of rat liver ribosomal subunits determined by equilibrium centrifugation¹⁰.

** The sum of NM^2/M where N = relative number of protein copies, assumed to be one and M = molecular weight (Fig. 2). "Minimum" values include only the "major" zones. "Maximum" values include "minor" zones. The fact that the "maximum" values are greater than the "minimum" values is coincidental, arising from the fact that the "minor" proteins on the average are larger than the "major" ones.

†† Obtained by determining the point at which the densitometer trace in Fig. 3 could be cut into equal parts. The values agree with the figure of 26,000 previously obtained from the total ribosomal protein of rat liver¹⁰.

‡‡ The observed molecular weight of protein divided by the observed weight average molecular weight of the protein.

§§ The number of zones which appear in Fig. 2. The maximum value includes the "minor" zones whereas the minimum value does not.

does not seem to have been considered explicitly: the rate of protein synthesis in *E. coli in vivo* (15–30 amino-acids/s/ribosome^{23,24}) is more than ten times greater than in the two eukaryotic systems, chicken oviduct²⁵ and rabbit reticulocytes²⁶ which have been examined. That differences in function should be found is not surprising in view of the striking differences in the make up of the ribosome.

I thank Mr R. Foulkes for the amino-acid analysis and Miss J. Shearman for technical assistance.

Effects of L-Asparaginase on Lymphocyte-Target Cell Reactions *in vitro*

L-ASPARAGINASE was, until recently, thought to be a specific antileukaemic agent. It has recently been shown, however, to be an immunosuppressive agent, inhibiting antibody production¹, lymphocyte transformation^{2,3}, the graft-versus-host reaction⁴, and graft rejection⁵. We have investigated its effects in an *in vitro* system in which rat lymphocytes react to monolayers of mouse embryo cells, first undergoing transformation and then lysing the latter⁶.

Lymph-node cells from grey hooded rats, aged 1½–3 months, were suspended in Dulbecco's medium with 20 per cent horse serum and were added to Balb/C embryo fibroblast monolayers grown in 60 mm Falcon Petri dishes. Before adding the lymphoid cells, the monolayers were irradiated with 1,500 rads cobalt-60 γ-rays. The cultures were incubated for 5 days and the free-floating lymphoid cells were then passaged on to fresh monolayers. Lymphocyte transformation began at 3 days, newly formed blast cells proliferated and, during the 5th to 7th days, large pyroninophil cells (LPC) developed which completely lysed the target monolayer by the 7th day.

L-Asparaginase of *E. coli* origin (Farbenfabriken Bayer, A.G.) was dissolved in phosphate-buffered saline and added to cultures at a final concentration of 2.5 i.u./ml.; the solvent only was added to control cultures.

Asparaginase completely inhibited lymphocyte transformation and a practically pure population of small lymphocytes survived as long as asparaginase was present (up to 9 days in these experiments). In control cultures, transformation and lysis of the monolayer occurred. Fig. 1 shows the distribution of lymphoid cell sizes at the 8th day in cultures with and without asparaginase, the former showing a typical small lymphocyte population, the latter showing a mixture of small and large cells.

At the time of transfer of a lymphoid cell suspension on the 5th day, when numerous LPC were present, the suspension was divided into two parts, each being subjected to serial doubling dilutions. Asparaginase to a final concentration of 2.5 i.u./ml. was added to one series and all the suspensions were added to fresh monolayers

Fig. 1. Distribution of sizes of rat lymphoid cells cultured on mouse embryo monolayers. *A*, Rat cells in asparaginase-free medium, cultured 5 days, then transferred to a fresh monolayer and recultured 3 days; *B*, rat cells in medium containing 2.5 i.u./ml. asparaginase, cultured 5 days then transferred to a fresh monolayer in asparaginase-containing medium and recultured 3 days. Cell sizes were determined in a Coulter Model B counter. Note the large proportion of large cells in the control culture (*A*) and their absence from the culture made in the presence of asparaginase (*B*). The columns to the left of the dashed lines represent cell debris.

and were incubated for a further 2 days. Asparaginase inhibited lysis of the monolayer. Microscopy showed that all LPC in these cultures disappeared within 24 h, leaving a population of small and medium-sized lymphocytes.

In order to see whether the inhibitory effect of asparaginase was reversible, the lymphocytes from 5-day and 9-day cultures that had been grown in 2.5 i.u./ml. asparaginase from the onset were collected, centrifuged, resuspended in fresh asparaginase-free medium and were then added to fresh monolayers. Blast cells first appeared 3 days later and increased in numbers subsequently. They appeared to be morphologically normal but they did not develop into lytic LPC. Instead, transitional forms between blast cells and macrophages developed and, during the next 3-4 weeks, there was a progressive growth of macrophages which, mixed with medium-sized lymphocytes, eventually covered the monolayer confluent.

In summary, addition of 2.5 i.u./ml. of asparaginase to rat lymphocyte-mouse embryo cultures prevented transformation of the lymphocytes to large pyroninophilic cells, and a pure population of small lymphocytes survived as long as asparaginase was present (9 days). When asparaginase was then omitted, the cells that remained were unable to transform into lytic cells and many macrophages developed. When asparaginase was added to cultures in which transformation was actively occurring, the transformed lymphocytes were rapidly destroyed.

It therefore seems that, when rat lymphocytes are exposed to xenogenic cells in the presence of asparaginase, either their transformation into large pyroninophilic cells is prevented or cells that do begin to transform rapidly die and disintegrate so that they are not observed. The second interpretation is supported by experiments (unpublished) showing that, in cultures containing both asparaginase and phytohaemagglutinin, the lymphocytes disappear almost completely within 3 days, although their survival is excellent when phytohaemagglutinin is omitted. It is interesting to compare these results with those obtained when asparaginase is used to inhibit antibody production *in vivo*. In the latter case, the optimum time for adminis-

tration of the enzyme is during the 24 h or so before exposure to antigen; administration at later times, when the lymphoid cells are already undergoing proliferation, is ineffective¹. In *in vitro* conditions, however, cells engaged in transformation and proliferation seem to be highly susceptible to the action of the enzyme. The reason for this discrepancy is not clear. It is possible that the immunosuppressive action of asparaginase *in vivo* may be related to the ability, demonstrated *in vitro*, of limited exposure to the enzyme to inhibit lymphocyte transformation for a long period subsequently. It is to be noted that even when asparaginase was omitted from the medium after having been initially present in high concentration, the surviving lymphocytes were unable to undergo transformation subsequently, although morphologically they appeared healthy.

Determination of *in vivo* Alterations in a Phenotype of Human Spermatozoa

A PHENOTYPE of rabbit spermatozoa for the dopa oxidase reaction has been reported¹. In the presence of L-dopa (dihydroxyphenylalanine), the cells develop melanin, proportional in amount or intensity to that present in the coat of the donor animal. These methods have been revised extensively to make possible a quantitative examination of the dopa reaction in human sperm.

Semen was taken from three donors selected on the basis of hair colour to increase the likelihood that they would vary in pigment genotype. Spermatozoa were separated from seminal plasma, washed in 0.9 per cent NaCl, and resuspended in Mann's Ringer solution². Glycerol was added to a sample of each suspension to provide a final concentration of 7.5 per cent v/v. Samples were cooled in the vapour of liquid nitrogen to 0° C in 60 s, and then to -196° C at an average rate of 200°/min. Experimental slides were incubated for 30 h in Sorensen's buffer (pH 7.4) to which was added 1:10,000 w/v of L-dopa. Two sets were reacted by the dopa oxidase method of Becker³, and one of these was subsequently stained for melanin by the hexamine-silver method of Gomori⁴. Control slides were processed through both reaction systems, but without L-dopa in the initial incubation.

After determining that Beer's law obtains in the dopa oxidase reaction, and that there is a definite absorption maximum for reacted cells, with controls having neither of these characteristics, the reaction in 100 cells per slide

was quantified by microspectrophotometry (my unpublished work); the plug method⁶ was used for the dopa oxidase reaction, at 405 m μ . Cells stained for melanin were studied by the two-wavelength method⁶, at 410 and 620 m μ . Calculations for the two-wavelength equations were made with the aid of the tables published by Mendelsohn⁷.

Table 1 gives the results of the work, with variance indicated by coefficients of variation. With respect to dopa oxidase activity in untreated cell suspensions, variance analysis gives $F_{2,297}=7.60$, $P<0.001$, and Tukey's test shows that each mean differs from every other. After freezing and thawing, there were significant differences among donors $F_{2,297}=7.22$, $P<0.001$, but in each case enzyme activity increased: $F_{1,594}=8.98$, $P<0.01$. A somewhat different pattern of alterations was evident in cells stained for melanin, after cryogenic treatment. Again, donors tended to differ with respect to their untreated cells, $F_{2,297}=2.85$, $P<0.05$, with those of T differing from those of H. But cells which were cooled to -196°C no longer displayed melanizing activities which differed among donors: $F_{2,297}=3.61$, $P>0.05$. The disappearance of mean differences among donors for melanin-stained cells may be a consequence of non-quantitative aggregation of silver particles on melanized cell surfaces in the hexamine-silver reaction. Coefficients of variation for both assays are most radically altered by treatment for the cells of the most deeply pigmented donor.

Table 1. DOPA OXIDASE ACTIVITY AND MELANIN REACTION IN HUMAN SPERMATOZOA; MEAN AND COEFFICIENTS OF VARIATION FOR 100 CELLS IN EACH CASE

Donor	Hair colour	Untreated	Dopa oxidase activity (M)		CV	Untreated	Melanin reaction (M)		CV
			CV	Frozen-Thawed			CV	Frozen-Thawed	
F	Black	1.9048	55.99	2.3315	86.77	286.42	32.39	306.85	40.34
H	Red	1.3979	54.09	1.5229	38.12	263.31	29.82	273.82	29.78
T	Blond	1.6965	89.10	2.0718	77.60	297.07	33.23	302.20	35.20

CV, coefficient of variation. M is given in arbitrary units^{6,8}.

The dopa oxidase phenotype is variable in the sperm cells of rabbit and man (ref. 1 and my unpublished work). It may be heritable, as are other variable sperm phenotypes⁸. The genetic basis of heritability might be haploid genetic activity in the cells during meiosis⁹, or alternatively, a function of the diploid genotype of the primary spermatocytes¹⁰. It is especially significant that cryogenic treatment can alter cell function in this system. Functional alterations have been found in association with the ABO phenotype of human sperm, which was first reported by Landsteiner and Levine¹¹ and by Yamakami¹²; these alterations are also a consequence of ultralow temperature treatment^{13,14}.

New Ocular Hazard of Mode Locking in CW Lasers

In a series of experiments to investigate threshold retinal damage produced by CW helium-neon lasers (wavelength = 632.8 nm), we have found that lasers with identical beam divergence and output powers but different amplifier/cavity parameters produce different amounts of retinal damage. The source of this discrepancy has been traced to mode locking in one of the lasers used.

The pupils of eight adult Dutch rabbits were maximally dilated with 2 per cent homatropine before anaesthesia. One eye of each animal was exposed¹ to one or other of two laser systems. The whole of the laser beam entered the pupil, and the time of exposure was controlled by a shutter. Retinal damage, when present, was observed with an ophthalmoscope as small white spots. These lesions when examined under the electron microscope showed damage in the pigment epithelium and receptor cells.

The first laser was a B18/3 8 mW helium-neon (He-Ne) model loaned by Scientifica and Cook Electronics Ltd (London). This device is a d.c. uniphase laser with a 2 mm \times 580 mm cavity run single mode. The second laser was a standard G9 He-Ne laser supplied by International Research and Development Co. Ltd, Newcastle, and, for reasons other than those reported here, was run multimode to obtain the maximum output power. A laser such as the G9 with a long cavity and high gain can be made to mode lock by introducing in the cavity an absorption

cell of excited neon. When mode locked, instead of producing a continuous output, the laser generates a train of pulses at a very high frequency. Typically a He-Ne system operating in that way might produce pulses of width about 2 ns at a rate of about 75 million/s.

Loss mechanisms in a multi-mode laser cavity, other than an absorption cell, can also mode lock the system. As intra-cavity losses were introduced into the G9 laser to vary its output power, this output was examined for mode locking. The detector was a reverse biased PIN diode (Hewlett Packard 5082-4220, response time 1 ns) coupled to a Tektronix oscilloscope (Type 561A fitted with a sampling dual trace unit type 3S76 and a sampling sweep unit type 3T77A).

Fig. 1 shows that the G9 laser was mode locking and producing neither a continuous output nor random giant pulses (these latter would not form a trace with the sampling oscilloscope). The pulses are seen to have a pulse width of about 1.5 ns and occur every 11-12 ns. The apparent pulse height depends on the rise and decay times of the photodiode and oscilloscope, and on the noise which may trigger the sampling unit to produce a broad base-line.

The usual type of power detectors used to measure CW laser outputs are incapable of resolving such short pulses and will indicate only a mean power level. The peak power in a mode locked pulse will be greater than the mean power by the ratio of the pulse repetition period to the pulse half-width. Taking the values we have given, and assuming that the pulses are roughly triangular in shape, this ratio is approximately 8. In fact the ratio of peak to mean power could be higher than this because the pulse width may be less than 1.5 ns. Pulse widths as low as 10^{-11} s have been reported from mode locked laser systems but for a He-Ne laser it is unlikely that this width would be less than about 0.3 ns, making the maximum power ratio 35-40.

Fig. 1. Output of the unintentionally mode locked helium-neon laser described in the text. Oscilloscope record of photodiode output versus time. The mean power was 1 mW and the apparent peak power about 8 mW. The apparent half-width of the pulse was 1.5 ns and the repetition period 12 ns, 5 ns per large horizontal division.

Table 1 shows that when both lasers were operating at the same mean power it was possible to damage the retina only with the G9 laser though the energy dose was one twentieth of that from the B18/3 system. Herein lies the danger with a laser in which mode locking can occur. Pulsed laser studies have shown that the parameter which determines whether the retina is damaged is retinal peak power density²⁻⁴. With a mode locked laser the output of which is monitored with a conventional power meter the retinal power density may be an order of magnitude more than expected.

Table 1. COMPARISON OF UNINTENTIONALLY MODE LOCKED AND NON-MODE LOCKED HE-NE LASER RADIATION AND RETINAL DAMAGE IN DUTCH RABBIT EYES

	Mean power (mW)	Peak power (mW)	Exposure time (s)	Total energy (mJ)	Damage to retina
Mode locked, G9 laser	5	40-200	15	75	Minimal supra-threshold lesions
Non-mode locked, B18/3 laser	5	—	300	1,500	No lesions

All the parameters were measured at the cornea.

We wish to point out the potential hazard of laser systems which might unexpectedly be operating in the mode locked manner, especially because it is not clear whether the maximum permissible retinal exposure levels given in the various codes of laser practice⁵ are derived from systems that were or were not mode locking.

Response to Criteria for the Designation of Persons working with Unsealed Radioactive Substances

HUGHES has outlined the derivation of criteria that he uses to decide if a worker using unsealed sources of radioactive material should be designated or not¹. Although I think that this general approach to the problem is appropriate, I would suggest that some of the numerical values of the parameters used in the derivation could be improved.

For the derivation of maximum activity to be handled at one time, in which intake of radioactive material resulting from an accident is considered the following points should be considered. (1) Hughes's premise that an individual will not be involved in such accidents more frequently than once per month led him to base his calculations on three-tenths of the monthly maximum permissible intake. Franke, Herrmann and Hunzinger² reported that only one radiation worker in five is likely to be involved in a radiation accident during a working life, so it would seem most restrictive to use the intake limit set by Hughes in this connexion. For designated persons the International Commission on Radiological Protection³ (ICRP), has stated that the maximum permissible quarterly dose should not exceed half the annual maximum permissible dose, and that if necessary this quarterly dose may be received as a single dose. By analogy, it would therefore seem appropriate to permit a non-designated worker a single intake of up to one half of three-tenths the annual maximum permissible intake, and I suggest that this is the figure that should be used in calculating maximum activity to be handled at one time.

(2) Based on the data of Franke, Herrmann and Hunzinger, Hughes selected a value of 10^{-5} for the parameter inhaled fraction of total activity handled (IFTAH). Donth and Maushart⁴ have published data which shows that in accidents involving gaseous or highly volatile radioactive substances, the IFTAH can be appreciably greater than 10^{-5} , and based on this data I would suggest an IFTAH value of 10^{-2} for gaseous and volatile sources, and 10^{-5} for all others.

When it comes to the derivation of maximum turnover per quarter, using small intakes from routine work as the basis of calculation, the figures derived by Hughes for radioiodines look unrealistically low compared with figures suggested in Publication No. 12 of ICRP⁵. This publication states that experience has shown that routine monitoring for internal contamination or for air contamination will rarely be needed, except when iodine isotopes at levels of a few hundred millicuries are handled. Other circumstances in which such monitoring might be required are also specified, but these are not relevant to conditions in universities and hospitals. The implication of this statement is that below such activity levels, intakes are most unlikely to exceed three-tenths of the maximum permissible intakes, and designation is therefore inappropriate. Hughes derived values of maximum turnover in experiments per quarter of 0.3 and 0.12 mCi for ¹²⁵I and ¹³¹I respectively, on the assumption that one hundredth of the activity used per quarter would be taken into the body. The ICRP guidance indicates that a more realistic intake fraction could be taken as 10^{-4} , and even this factor allows a reasonable margin of safety. I suggest therefore that a value of 10^{-4} be used for the fractional intake of the quarterly turnover, and that this value be used for all other radionuclides as well as for the radioiodines.

⁴ Douth, H. H., and Maushart, R., *Health Phys.*, **12**, 106 (1966).

⁵ *International Commission on Radiological Protection, Publication No. 12* (Pergamon, Oxford, 1969).

Defence of Criteria for the Designation of Persons working with Unsealed Radioactive Substances

BUSH's comments (in the preceding communication) are a welcome development of the proposals in my earlier letter which are intended as a broad administrative guide capable of refinement if more precise levels of activity are to be set.

The maximum activity to be handled at one time would be increased by a factor of 6 if Bush's suggestion (1) is taken. But my original figures have not proved restrictive for most users in the University. Suggestion (2) makes a very important revision of the IPTAH in the case of gaseous and volatile substances and the figures for ⁸⁵Kr and ¹³³Xe in my letter should be adjusted accordingly.

Bush's suggestion for increasing the maximum turnover in experiments per quarter by a factor of 100 is inferred from the guidance of the ICRP¹ on the need to monitor individuals for internal contamination when handling gaseous or volatile materials and it would be very helpful if explicit recommendations could be made on this point. If the values are increased by a factor of 100, however, the need to provide individual monitoring for external radiation has to be considered because the activities of the sources will be appreciably higher than the levels set by the ICRP¹ for the introduction of such monitoring.

I am hoping that this correspondence will lead to the eventual inclusion in the appropriate codes of practice of further guidance on the levels at which designation is necessary.

Marijuana and Memory

THE effects of marijuana are not consistent from subject to subject¹. Any discussion of its effect on human memory (such as refs. 2 and 3) must therefore consider whether valid generalizations can be drawn from the subjects who have been examined. One way of minimizing individual differences is to use subjects as their own controls, as is done in the present study which investigates the effects of marijuana on the recall of narrative material.

The subjects were eight men and women aged from 22 to 37. All but one were college students, and all had used marijuana several times before the experiment. Each was tested singly in two sessions separated by more than a month. In the first session, half of them were given marijuana and half acted as controls; in the second session, the roles were reversed. Those receiving the drug were given two marijuana cigarettes the tetra-hydro cannabinol content of which had not been ascertained. After smoking both, each subject was allowed to relax or read. Five minutes later the experimenter asked the subject whether he felt "high". All subjects answered affirmatively.

The experimenter, who remained in the same room throughout the test, then gave the subject a copy of Bartlett's *War of the Ghosts*⁴, and told him to read it through twice, at his own speed. When the subject had finished, the story was removed. Fifteen minutes later

the experimenter gave the subject a pen and paper and asked him to recall as much of the story as he could accurately remember, using the same words and phrases if possible. When the subject had finished, the session was over. The control subjects were put through the same test without taking marijuana.

The protocols were subjected to King's method of analysis⁵ which involves determining: (1) The total number of words in each subject's version of the story. (2) The number of "content words" with the exclusion of all articles, prepositions, conjunctions, and so on. Content words must have appeared in the original story, but can be misspelt or out of sequence. (3) The number of two word sequences in the recalls which had appeared in the original. (4) The number of correctly recalled four word sequences. (5) The number of "idea units", appearing in the recalls, as defined by a division of the original protocol into such units. Because this task required a certain amount of arbitrary judgement, the estimation was made by three arbiters who did not know the subjects or the conditions of the experiment. Their three scores were averaged to give the idea score for each recall. Table 1 shows the results of the analysis.

Table 1. COMPARISON OF RECALL MATERIAL UNDER MARIJUANA (M) AND IN CONTROL CONDITIONS (C)

Subject	Total words		Identical content words		Two word sequences		Four word sequences		No. of idea units	
	C	M	C	M	C	M	C	M	C	M
S ₁	227	214	66	66	45	30	9	5	52	42
S ₂	267	256	67	59	39	49	10	11	53	55
S ₃	234	155	61	27	41	17	9	1	50	28
S ₄	55	45	15	12	11	1	2	0	12	5
S ₅	170	159	42	30	31	17	6	4	34	26
S ₆	265	221	73	47	51	36	7	10	50	32
S ₇	215	197	63	51	39	34	9	6	40	40
S ₈	177	204	68	53	32	44	6	12	47	40
Total	1,610	1,451	455	345	289	228	58	49	338	268
Average	201.3	181.4	56.9	43.1	36.1	28.5	7.3	6.1	42.3	33.5
	$t=1.84$		$t=3.69$		$t=2.72$		$t=0.91$		$t=3.10$	
	n.s.		$P<0.005$		$P<0.025$		n.s.		$P<0.01$	

Seven of the eight subjects wrote less under marijuana than in the control condition. On the binomial test for one-sample cases⁶ this effect is significant at the 0.035 level. The difference between the total scores for two conditions, however, was not significant. When only the content words are considered, not only do the subjects perform worse under the influence of marijuana ($P=0.035$), but the number of recalled content words is also significantly less in this condition ($P<0.005$). The means were 56.9 and 43.1 for control and marijuana conditions respectively. The difference was evaluated by the t test for correlated means⁷.

With the two word sequences, only six subjects did worse under marijuana than in the control condition. This effect was not significant. When the total number of two word sequences in the two conditions is considered, however, the difference between the two means (36.1 and 28.5 for control and marijuana conditions respectively) is significant at above the 0.025 level.

The final index was the number of idea units in the recalls. Once again, subjects under marijuana tended to do worse but the trend was not significant. The means for the marijuana and the control conditions were 42.3 and 33.5 respectively ($P<0.01$), indicating that when there was an effect, it was significant.

The result of being "high" in this experiment was that subjects were not as capable of reproducing material which they had recently read. Not only were subjects worse at recalling exact words, they were also worse at recalling the ideas of the story they had just read. It is also noteworthy that the degree of impairment is significant. One can thus expect more than minor differences in behaviour as a result of smoking marijuana. The nature and direction of these differences await further study. But although individuals did do worse under marijuana, they were still able to read, remember and write when they needed to.

One difficulty with this type of research is in determining the locus of the effect on memory; the methodology made it impossible to know whether the same amount of information entered the memory faculties before the subjects were asked to recall the material. If this were so, then the effects of marijuana would not be on memory but on the input of information before it can enter the memory. On the other hand, the material may enter the memory stores equally well in control and in "high" conditions, and the difficulty may be with retrieval, as Weil and Zinberg suggest³. This problem could be answered by having subjects read the same material under marijuana and then asking some to recall it under marijuana while others recall in control conditions.

I thank Miss C. Edwards, Miss M. Coombs and Mr K. Stang for acting as arbiters. This study was conducted while I was a post-doctoral fellow at the University of California at Berkeley.

Effect of Item Similarity on the Speed of Memory Search

Chase and Posner reported to the Midwestern Psychological Association in 1965 their investigation of the speed with which subjects determined whether a target letter (TS) was present or not in a comparison set (CS) when the letters were drawn from an acoustically similar population (AC), a visually similar population (VIS) or a neutral population (N), and the stimuli were presented visually. TS was presented either simultaneously with CS (visual comparison search), or before CS (visual recognition search) or after CS (memory search). From the evidence that verbal material is coded auditorily in memory^{1,2} they anticipated that acoustic similarity might affect speed in this task, changing the slope of the function relating reaction time and the number of letters in CS. In fact, only visual similarity had an effect, increased visual similarity increasing the reaction time in the visual comparison search and memory search. Chase and Posner concluded that a visually coded representation of the stimulus was used in these situations.

We have investigated whether acoustic similarity has an effect when stimuli are presented auditorily. The neutral and acoustically similar populations from Chase and Posner's experiment were used, with G replacing Z in the latter to allow for English pronunciation. The populations were A, D, H, I, M, Q, Y, Z (neutral) and B, C, D, E, P, T, V, G (acoustically similar). Only the memory search is possible when stimuli are presented auditorily. There were eight subjects, each serving in all six conditions. Conditions differed in the size of CS (1, 2 or 4) and the population of letters (N or AC). On each trial a CS drawn at random from the appropriate population was read out at a rate of two items per second, then a TS after a pause of 1 s. After a series of practice trials, four for each condition, the six conditions were given in random order with thirty-two trials in each condition. On half the trials TS was present in CS and in half it was not;

Fig. 1. Graph showing the mean time to decide whether a target letter was present or absent in a comparison set (CS) of letters, when letters were drawn from a neutral (N) or an acoustically similar (AC) population of letters. Results for positive responses (○—○) and negative responses (×---×) shown separately.

the two types of trial occurred in random order. Reaction time was measured by a timing device operated by a voice key; the timer started when the experimenter spoke the target letter and stopped when the subject responded "yes" or "no". If the subject made an error, the trial was rerun at the end of the condition.

The results were analysed by a four-way analysis of variance with each effect tested against its interaction with subjects. Fig. 1 shows that reaction time increased linearly with the size of CS (the linear trend was significant at the 0.001 level), and the increase was more rapid in the AC conditions (the difference in linear trend between N and AC conditions was significant at the 0.001 level). Negative responses were slower than positive ($P < 0.01$), which agrees with Nickerson's findings³ that mis-matches take longer than matches. This difference was greater in the AC conditions ($P < 0.025$), but Fig. 1 shows that this was not the case for all values of CS; in fact there was a significant triple interaction between stimulus similarity, size of CS and type of response ($P < 0.025$) so the interaction between stimulus similarity and type of response will not be discussed further. No other effect was statistically significant.

The result confirms findings such as those of Sternberg⁴ and Chase and Posner that reaction time in memory search is a linear function of the number of items in CS; this evidence suggests that TS is compared with each member of CS in turn. The result, compared with that of Chase and Posner, implies that the way stimuli are stored in memory in this task varies with the modality of the stimuli. The result does not, however, imply that each comparison of TS with a member of CS took longer when the items were acoustically similar than when they were from the neutral set. If this had been the case the function for the AC conditions would have been above that for the N conditions throughout, as in the result of Chase and Posner, whereas it was below that for the N conditions for CS1 and CS2. This implies that increased acoustic similarity speeded up this comparison process rather than slowing it down; therefore some other process must be sought to account for the change in slope associated with the change in acoustic similarity.

One possibility is that the subject decides not merely that some member of CS matches TS sufficiently closely to justify a positive response, but first decides which member of CS matches TS most closely, then decides whether a positive response is justified. To do this, every member of CS must be examined, even when a close match of TS with a member of CS is found early in the series of comparisons. That this is done is implied by the similar

slopes for positive and negative responses, as Sternberg⁴ pointed out. If the time taken on this decision, as to which member of CS matches TS most closely, is a linear function of the size of CS, and if the decision is more difficult and takes longer when the items are drawn from a similar population than when they are drawn from a neutral population, then the obtained result may be deduced.

Eye to Eye Transfer of an Early Response Modification in Chicks

ZEIER¹ reported that trained loss of a cliff-avoidance response did not transfer from eye to eye in the chick whereas imprinting and pattern discriminations do transfer in birds. He suggested "It is possible therefore that tasks involving responses for which there is a strong inherent disposition are more easily transferred from eye to eye than are reactions that run counter to an innate response tendency". I have observed, however, transfer of a learned response that runs counter to the "innate" tendency of chicks to peck small targets.

The basic procedure has been described^{2,3}. When neonate white Leghorn cockerels are presented with a small target, nearly all peck it within 10 s. Repetition of this response can be suppressed by a single presentation of the target coated with an aversive liquid such as *n*-propanol⁴ or methyl anthranilate^{2,3,5}. I have used this response modification to study transfer by training chicks with one eye occluded followed by testing after 16–128 min with the contralateral eye occluded.

The original occluder was a Band-Aid "sheer spot" (Johnson and Johnson), a 22 mm circular adhesive plastic with a 10 mm central gauze pad; the pad was centred over the eye. In a second experiment two "sheet spots" were overlapped to a long diameter of 26 mm. Each occluder was inspected before each target presentation and pressed down or replaced as necessary. Each monocular occluder, whether shifted or not, was replaced with a fresh occluder before the test trial to equalize handling conditions. Chicks tested binocularly wore a monocular "occluder" left open rostrally to permit vision; it was also replaced. The ability of "sheer spots" to block vision was confirmed by presenting the target to chicks ($n=40$) with both eyes occluded. No pecking occurred in 97.0 per cent of 200 presentations; the comparable rate for chicks with monocular or binocular vision was 8.3 per cent.

The training target, a 3 × 5 mm microminiature lamp, was dipped into methyl anthranilate just before presentation to each experimental chick or into water before presentation to each control chick. The lamp was dry during all test presentations. The novel test target was a dry 3 mm stainless steel bead⁵. The chicks were individually blind-coded between training and testing. The interval between training and testing was 16, 32, 64, or 128 min in the first experiment; the results were independent of the interval and are pooled in Table 1 (groups 1–4). A single training-testing interval of 120 min was used in the second experiment (Table 1, groups 5–10). Chicks

Table 1. DISCRIMINATED TEST RESPONSE OF CHICKS TO THE TRAINING TARGET (LAMP) AND A NOVEL TARGET (BEAD)

Group	Condition	Train-test interval (min)	Test response					
			Lamp			Bead		
			A	P	Per cent A	A	P	Per cent A
1 Exp.	L-R	16-128	31	9	77.5	7	33	17.5
2 Exp.	R-L	16-128	29	11	72.5	6	34	15.0
1,2 Exp.	L-R, R-L	16-128	60	20	75.0	13	67	16.3
3 Control	L-R	16-128	8	32	20.0	0	40	0.0
4 Control	R-L	16-128	6	34	15.0	2	38	5.0
3,4 Control	L-R, R-L	16-128	14	66	17.5	2	78	2.5
5 Exp.	L-R, R-L	120	17	3	85.0	3	17	15.0
6 Exp.	L-L, R-R	120	13	7	65.0	0	20	0.0
7 Exp.	Binocular	120	11	9	55.0	1	18	11.1
8 Control	L-R, R-L	120	2	18	10.0	0	20	0.0
9 Control	L-R, R-R	120	3	17	15.0	0	20	0.0
10 Control	Binocular	120	3	17	15.0	2	18	10.0

Experimental groups (Exp.) were trained to avoid the lamp by coating it with methyl anthranilate; control groups were "trained" on the lamp coated with distilled water; L, left; R, right; L-R condition signifies training with left eye open, testing with right eye open; R-L condition signifies the reverse; L-L and R-R signify training and testing with the same eye; A, avoided target; P, pecked target.

trained monocularly transferred the peck avoidance response to the contralateral eye (groups 1, 2 and 5). In the first experiment (groups 1 and 2) 75 per cent of chicks trained monocularly avoided the lamp target when tested with the untrained eye; in a separate experiment² with normal binocular training and testing, the mean avoidance was 74.5 per cent and the range was 62.5 to 85.0 per cent in twelve groups ($n \approx 40$ per group). In the second experiment, chicks tested with the untrained eye (group 5) had a higher avoidance than chicks tested with the trained eye (group 6) or binocularly (group 7) but the differences were not statistically significant ($\chi^2=1.20$, $P>0.2$; $\chi^2=2.98$, $P>0.08$, respectively). There was no evidence of significant lateralization; the pooled avoidance of all L-R chicks (trained with the left eye, tested with the right eye) did not differ significantly from the pooled avoidance of all R-L chicks (41/50 versus 36/50; $\chi^2=0.90$; $P>0.3$). The test with the novel bead target ruled out a general performance deficit as a factor in the avoidance response; the results demonstrate that peck performance *per se* was normal, because 82.5 to 100 per cent of each group pecked the bead.

The successful interocular transfer of trained loss of "innate" pecking behaviour runs counter to the generalization suggested by Zeier¹. Possibly the explanation is to be sought in one of the other reported determinants of interocular transfer in birds, for example position of the relevant stimulus in the visual field⁶.

I thank Mayme Y. Bailey and Mary W. Garman for assistance.

Faeces of the Medicinal Leech, *Hirudo medicinalis*, are Haem

The pigmented tissue around the gut of the blood feeding leech, *Hirudo medicinalis*, was regarded by Moquin-Tandon in 1826 (ref. 1) as a liver. Spiess² challenged this concept on the grounds that the pigmented tissue was not

derived from the gut, but he agreed that it was a functional liver even if it was not a morphological or an embryological one.

Spiess examined the faeces chemically and concluded³ that bile pigments were excreted in the faeces, further confirming his belief that this tissue was indeed analogous to the vertebrate liver. He presented⁴ a new theory of the evolution of the leech liver based on his identification of bile pigments. Fukui, apparently unaware of Spiess's work, identified⁵ the faeces as haematin and could not detect bile pigments or haematoporphyrin in the faeces or even in the whole leech. He concluded that the ingested haemoglobin is split into globin, which is digested, and haematin, which is excreted in the faeces.

I have attempted to resolve this conflict by starving *H. medicinalis* and then by feeding them on rat blood. The faeces were collected and assayed. The aqueous solution of fresh faeces was green and had an absorption spectrum with a maximum at 397 nm and plateaux of 565 (broad) and 605 nm. When made to 1.0 N HCl, the solution turned reddish brown and absorbed at 394 and 655 nm with plateaux at 520 and 550 nm. When made to 1.0 N NaOH, the solution turned green again and absorbed at 390 and 590 (broad) nm. The peaks at 397, 394 and 390 nm were very narrow and much more intense than the others, qualifying as Soret bands, a characteristic of all tetrapyrrole rings, that is, porphyrins⁶. Illumination with ultraviolet through a Wood's filter (365 nm) did not elicit a fluorescence in acid, neutral, or basic solutions of faeces. Thus the porphyrin is not "free" but has its pyrrole nitrogens completely bound. Tests for iron in the faeces were negative unless the samples were ashed or treated with reagents, such as NaOCl or H₂SO₄, which liberate the iron. Iron was detected using KCNS, K ferrocyanide, and thioglycolic acid⁷. A porphyrin containing bound iron is a haem; therefore, the faeces contain a haem.

The presence of a haem was confirmed by the emission of a bright red orange fluorescence under ultraviolet illumination after treatment with concentrated H₂SO₄ which liberates the iron and frees the porphyrin⁸. The same fluorescence was also obtained using acetic acid with sodium hydrosulphite⁹. Further confirmation was obtained by converting the faeces to pyridine haemochromagen⁶. No bile pigments were detected in the faeces using the Gmelin reaction⁹ and the sensitive Schlesinger reaction¹⁰. The faeces seem to consist almost entirely of haem. Tests for protein, reducing and non-reducing carbohydrates, and lipid were all negative to at least the 1 per cent level.

Spiess's results can be explained by appraising his methods³. *H. medicinalis* only defaecates occasionally, from once a week to once a month. In order to obtain samples of a sufficient size, he collected the faeces over a period and concentrated the sample by prolonged boiling. This heat treatment cleaved the tetrapyrrole ring, liberated the iron and did, in effect, leave him with bile pigments.

In conclusion, my investigations show that the faeces of *H. medicinalis* are a haem. Fukui was right and Spiess was incorrect. The leech system described here is presented as a model for blood feeding animals. More important, perhaps, is that *H. medicinalis* is defaecating almost pure haem.

This investigation was supported in part by a predoctoral fellowship from the US National Institutes of Health.

Capric Acid as a Larvicide and an Oviposition Stimulant for Mosquitoes

CONCERN about the excessive use of insecticides has focused attention on less toxic materials and revived interest in certain fatty acids¹⁻⁴. Insecticidal properties of some of these acids (especially of their potassium soaps) have long been recognized and this has led to their widespread use in sprays^{5,6}.

During a field assessment of capric (decanoic) acid as a mosquito larvicide, a potentially more valuable entomological use for this acid was found: as well as being a larvicide, its addition to artificial pools⁷ made them strikingly attractive oviposition sites for the mosquito, *Culex restuans* Theobald.

The larvicidal activity was evident after capric acid was added in amounts equivalent to 150 and 300 p.p.m. each to five pools randomly selected along with six untreated pools or controls in a four by four array. Larvae died in 3 days after treatment at a mean maximum temperature of 26° C and in 14 days at 10° C. During this same period the pools were unacceptable to mosquitoes as oviposition sites. This "repellent" period was followed by several successive phases with distinct characteristics: (1) pools gradually lost their repellency and became acceptable oviposition sites; (2) pools became exceptionally attractive for oviposition; (3) treated pools gradually became no more acceptable than untreated pools. By this time the treated pools, which during phase (2) had turned opaque brown, had lost their colour and became as clear as untreated controls. Maximum acceptance for oviposition occurred 10-14 days after application of 150 p.p.m. and 14-21 days after application of 300 p.p.m. of capric acid. After the "repellent" period the treated pools were no longer lethal to mosquito larvae or other arthropods.

During 2 months after treatment 2,866 egg rafts of *C. restuans* were deposited in ten treated pools and only five rafts in six untreated pools.

Pools treated with capric acid but containing no detectable, or very few bacteria of the family Pseudomonadaceae (identified by G. E. Bucher, Research Institute, Bellevue, either did not "attract" ovipositing mosquitoes or did so only after a relatively long time. The same pools, however, were brought to the conditions found in phase (2) by inoculating them with 100 ml. of water from an "attractive" pool. They were then used by the mosquitoes for oviposition. Treated pools that had passed through the various phases of "attractiveness" could be returned to phase (2) by adding more capric acid. Evidently relative numbers of active bacteria in the pools determined the degree to which mosquitoes used them for oviposition, and this was coincident with the appearance of the water—brown and opaque with many actively reproducing bacteria as in phases (1) and (2) and later clear when the bacteria died and reproduction was minimal as in phase (3). Evidently bacteria responsible for the attractiveness were present in most of the pools, and capric acid acted as a fertilizer, supplying the carbon needed for their rapid growth.

Water taken from an "attractive" pool was clearly preferred to tap water in laboratory tests with other species of mosquitoes. Relative numbers of eggs or egg rafts laid in "attractive" compared with tap water were 1,190

and 71 for *Aedes aegypti* L.; 265 and 55 for *Culex pipiens* L.; and 24 and 4 for *Culex tarsalis* Cop.

Substances that can aggregate individuals of a field population at an appropriate stage should make a valuable contribution to control programmes, especially perhaps to those involving sterilization at a natural focus. Being non-persistent, relatively inexpensive and only briefly toxic to aquatic life (not necessarily a disadvantage in artificial pools), capric acid appears to hold great promise as such a substance.

Increasing Frequency of the Typical Form of the Peppered Moth in Manchester

THE murk of nineteenth-century Manchester fostered the melanic form carbonaria of the peppered moth, *Biston betularia* (L.). The subsequent spread of this form, at the expense of the pale coloured typicals, throughout industrial regions in Britain and elsewhere in western Europe, is a striking example of rapid evolutionary response to a changing environment.

Records of *B. betularia* in Britain indicate that the incidence of the melanic form in industrial regions increased swiftly during the past 100 yr, but precise data on the rate of change are regrettably lacking¹. In Manchester the black form was prevalent by 1900, although typicals still occurred. The only large sample recorded from the area was taken between 1952 and 1964 at Didsbury, about 4 miles from the city centre^{1,2}. In all, 760 moths were collected, consisting of 749 carbonaria and eleven of the intermediate melanic form insularia, typicals being unrepresented.

The environment of the peppered moth is again changing. Smoke control, started in 1952, has led to a marked reduction in the amount of soot in the air. Old, buildings blackened by smoke are being cleaned, and new ones are being constructed of light coloured fabrics. To investigate whether these current changes are reflected by the population of *B. betularia* and of other polymorphic species of moths, between 1966 and 1969³ we collected the moths in mercury vapour light traps and assembling traps at sites between Prestwich to the north and Jodrell Bank some miles to the south of the conurbation. In all, 972 *B. betularia* were recorded of which twelve were insularia and twenty-five were typicals. By Fisher's factorial test the difference between the frequency of typicals in this sample and in the returns for 1952-64 is very highly significant.

The form insularia is variable in phenotypic expression, sometimes approaching the typical in appearance. In the Manchester area specimens tend to the darker rather than the paler end of the range of variation, so that in this region there is no danger of confusing the two forms. After correspondence with Mr H. N. Michaelis, the collector of the earlier material, and examination of some of his specimens in the Manchester Museum, we are convinced

that both sets of samples have been scored using the same criteria.

Some of the collecting sites at the southern end of the transect are quite rural in character, but the results are uniform over the entire length. Considering only moths in Didsbury and in Longsight, a more polluted locality two miles to the north, we obtained eight typicals and two insularia in 364 individuals. The frequency of typicals is again significantly different from the earlier one obtained from almost the same area ($P < 0.0001$), suggesting that there has been a recent resurgence of the typical form deep in the Manchester conurbation. Evidence of a small but significant increase in frequency of typical moths in the Liverpool area following the introduction of smoke control has been reported by Clarke and Sheppard⁴.

We thank colleagues in the Department of Zoology, Manchester University, for collecting samples.

Synthesis of a Mucous Cuticle by a Zoanthid

MANY zoanthids (Coelenterata, Zoantharia) are known to produce a secretion which lies external to the epidermis¹. This structure is termed a "cuticle". Although it has been assumed that the cuticle is secreted by the epidermis, direct evidence of this is lacking. The source of substrates used in the synthesis of the cuticle is also unknown.

During studies on the movement of photosynthetic products of zooxanthellae to the tissues of their animal hosts, it was noticed that in *Zoanthus* sp., photosynthetically fixed ¹⁴C moved from the algae in the animal's gastroderm to the epidermis, and was then incorporated into the substance of the cuticle as it was secreted by the epidermis.

Specimens of *Zoanthus* sp. were collected at Punta Piñasco, Baja California, Mexico. They were maintained in seawater aquaria at 20°-23° C under constant aeration and daily illumination of about 1,000 foot candles. They were used in experiments within 5 days after collection.

The animals were incubated in the light and in the dark for 1 h in seawater to which NaH¹⁴CO₃ was added to give an initial activity of 10 µCi/ml. Specimens incubated in the light were then transferred to unlabelled sea water in the light. Specimens incubated in the dark were first placed in unlabelled seawater in the dark for 6 h before transfer to the light, to ensure that residual unincorporated H¹⁴CO₃ had been washed out from the tissues. 6 h after the end of the incubation, one dark-incubated and one light-incubated specimen were fixed in Bouin's solution. The dark-incubated specimens were then separately transferred to the light in fresh unlabelled seawater and all were exposed to daily illumination. At daily intervals for the first 10 days, and every 2 days subsequently for a total of 25 days, light and dark-incubated specimens were fixed. Specimens were prepared for autoradiography according to a method previously described^{2,3}. Paraffin embedded sections were cut at 5-7 µm, and tissues were exposed to Kodak NTB-2 liquid emulsion for 9 days and developed as suggested by the manufacturers.

Zooplankton was collected in coastal waters 33 to 35 m from Boothbay Harbor, Maine ($43^{\circ} 48' N$, $69^{\circ} 38' W$), simultaneously at the surface and 10 m and 30 m down, using 20 cm Clarke-Bumpus closing samplers hauled between 2 and 3 knots for 15 min. Tows were made at approximately hourly intervals from morning to evening on the pre-eclipse (control) and eclipse days. In the laboratory, the zooplankton was sorted into major taxa, and the numbers of each taxon per $10 m^3$ of water per sample were calculated. The time at mid-eclipse was 1348 EST (Fig. 1) when about 94 per cent of the Sun was obscured. At Boothbay Harbor the Sun was at an altitude of 34° ; sky clear with visibility about 15 km, wind 5 knots from the SW, and the sea calm. On the pre-eclipse day the sky was generally clear, but between 1300 and 1400 h a one-sixth cover of stratocumulus clouds passed over the sampling area; sea conditions were calm throughout the day.

There were nineteen taxa in the samples, five of them in abundance, accounting for over 90 per cent of the plankton—copepods, decapod larvae, chaetognaths, cirriped larvae and gastropod eggs. Copepods were dominant, constituting 70 per cent of the total. Of the sixteen species in the samples only two were numerous—*Pseudocalanus minutus* and *Calanus finmarchicus* (more than 85 per cent of the total copepod species).

The vertical distributions of the zooplankton differed significantly (Figs. 2 and 3). Adult chaetognaths (*Sagitta elegans*) were concentrated near the bottom on both days although numbers in the upper 10 m increased slightly in the evening. Larval decapods were concentrated at 10 m during daylight and moved to the surface after sunset (about 1756 h EST) on both days. The vertical distribution of larval cirripeds was more variable. They were most numerous 10 m deep during daylight; notable exceptions occurred during the eclipse, when cirripeds were concentrated at 30 m between 1100 and 1230 h, and again after sunset, when they were abundant over the bottom. The non-motile gastropod eggs were widely distributed among the depths sampled on both days.

Copepod distributions were also variable; concentrations increased at the surface on March 7 during the mid-
